Yes. You can either get an add-on board (from Atari, for one, but I forget the model number. Came out last year) or software to emulate 80x24 on the Graphics 8 screen. There are several programs I am aware of which do the latter, as well as several VT100 emulations, as well as several programs with various other capabilities. Unfortunately, the ones that do a good VT100 generally don't have very versatil file-transfer, and vice versa - for all I know, it may be a memory limitation! I'd suggest getting several programs of different strengths, and using whichever one suits your needs of the moment.

> 3) Assuming you can do the above stuff, is there software to emulate
> a VT-100 terminal? It would be nice if it could also
> dump the screen to disk and/or printer on operator request.
> If not Vt-100, how about some other terminal (other than
> a "glass TTY" with no cursor control at all!).

I recommend OmniCom if you want a wide variety of capture/file-transfer modes, plus a half-hearted VT100 emulation; John Dunning's port of Kermit65 (from the C64) for TERRIFIC VT00 and VT52 emulation if you can stand having only Kermit file-transfer and NO "print screen;" 850 Express! or 1030 Express! if you want screen-capture and screen-print on a dumb-TTY terminal. Person-ally, I prefer J.D's ported Kermit65. I wouldn't use "V-T-10-squared" if you paid me; it's not very good at being a VT100, and there's NO capture.

> Mike Ciaraldi
> University of Rochester Computer Science

Mike, I'm at BSU in Indiana, but I'm a Rochester native. Have you checked Leon's on CLinton Ave. downtown? If they don't carry Atari stuff I don't know who will.

You might also try calling Chuck Antonelli at (cross fingers) 461-3900 or 3920, mention my name, and ask if he still does Atari business. He might be able to at least inform you of the current state of availability.

At worst, if you don't have this up and running by three weeks from now, I will be coming back to Rochester for my Spring (?) Break and will bring my disks so you can at least SEE the programs and maybe copy the PD stuff. Let me know if this is good for you and your friend!

872. Latest on CDY Consulting - reply to question by Nick DiMasi

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-08 04:24:19 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8802080424.AA17109@mitre-bedford.ARPA>
Source record: 117226

Nick, your message (and I think an earlier one) got here OK via linus, but there was no clue as to a return path. So I am replying here, in part because the info may be of general interest.

Nick DiMasi reports that the former CDY phone number has been disconnected and there is no listing for CDY Consulting. I haven't tried the number, but I did get an e-mail reply from David Young a few weeks ago saying that in the future I should call Wes Newell of Newell Industries to place orders for CDY's products. Between the lines was the explanation that sales volume for 8-bit products has dropped to the point that it was not worth David's while to keep handling the sales. He also told me many months earlier that he was just plain TIRED of programming, and that it was no longer fun, as it once was.

I guess we can all understand how the combination of factors might bring him to that decision. Having gotten to know David a bit by e-mail correspondence and a couple of long phone calls these past couple of years, I am certain that he will continue to provide technical support when it is really needed. He is both a formerly-avid Atari 8-bit computer enthusiast and a conscientious (retired) businessman who has pride in his creations. He won't let us down.

Meanwhile, orders for OMNIVIEW and OmniCom can be placed through Wes Newell at Newell Industries, 602 E. Highway 78, Wylie TX 75098. Newell's phone number is (214) 442-6612. Newell Industries also sells the "Newell Board", more officially known as the "256KXL" memory upgrade board, which among other things lets you run a full SS/SD RAMdisk. OMNIVIEW256 includes resident software to run the RAMdisk, by the way. Having used the RAMdisk as my second disk drive for a couple of years now, I can say that it's the only way to fly. It cuts down the time to load your favorite word processor or communications program or to hop back to DOS to a couple of seconds, giving the illusion of a much bigger, faster system. Also, the 256KXL board lets me run an 80K byte text buffer with CDY's OmniWriter 80-column word processor, and simultaneously the full-sized RAMdisk!!! Saving files to RAMdisk is a very quick operation.

The Newell board will also act pretty much like a 130XE (and STILL has enough memory left to run the RAMdisk!). There is a slight compatibility problem, which affects some but not much software. Newell suggests a fix for this using a switch to select two different modes of operation, and I worked out a patch to his board that should make all commercial software work correctly (though I have never tried it out). Info on that patch is available on request to me, and if I ever get around to it, I will send the info to Newell so you may be able to get it with the board if you buy one.

So, I'd like to express my thanks to David Young for making 80-column screen I/O available to us 8-bit users, as well as the earlier OMNIMON resident debugger which I have found mighty useful on occasion. I hope he will

eventually get over his feelings of "burnout" and rejoin the ranks of Atari 8-bit hobbyists in his "retirement". Thanks for a lot of nice software, David!

-John Sangster / jhs@mitre-bedford.arpa

I have no financial connection with CDY Consulting or Newell Industries, nor, alas, anyone else except my creditors, my employer, and Uncle Sam.

Let's try this addressing then ..... !

Date: Sun, 7 Feb 1988 14:18 EST
From: Chuck Reid <CCSCHR@UWOCC1.UWO.CDN>
Subject: Kermit-65 under ATARI DOS 2.5 using 130XE Ramdisk; Help!
To: Atari Digest <INFO-ATARI8@SCORE.ARPA>

Pick a question, any question ... ?

I located a bug in John Dunning's Kermit-65 application, often mentioned in this Digest; with John's help I was able to build a patch for the problem. This seems to be the first of many problems to eliminate before before I can successfully port Kermit-65 to my desired operational environment; Kermit-65 doing its Upload/Download to the Ramdisk on the ATARI 130XE using ATARI DOS 2.5. I am open to suggestions on the DOS 2.5 part of this implementation!!

I think I am breaking new ground in this area in that the Kermit-65 bug that I patched dealt with K-65 not actually accepting 8 (eight) for the 'default-disk' option. DOS 2.5 supports its Ramdisk as drive D8:, I think most other implementations try to look similar to this config? No one else seems to have mentioned this problem, therefore, Happy Ground-breaking!

DOS 2.5 when booted will always load the 850 interface if it finds this device powered on. This happens just after the Ramdisk is initialized. I then load K-65 from the DUP.SYS menu and K-65 has problems with what DOS 2.5 has done to the 850, claiming the "850 is not responding".
- How does one prevent DOS 2.5 from loading the 850?
- How does one get DOS 2.5 to load a piece of object code as an AUTORUN SYS file like DOS 2.0?

My circumvention is to turn off the 850 while DOS 2.5 is loading and then power it back up before loading K-65. This works fine but is clumsy as hell and will definitely shorten the life of my 850!!!
Once K-65 is loaded OK and my patch is on to support drive D8:, everything works as advertised!! D/Ls to the D8: Ramdisk are faster and quieter (no constant start/stop of my disk drive for each disk block received; This is what I am really trying to accomplish, elimination of the disk drive wear and tear associated with Kermit transfers)!!
So at this point, I can get the data to the Ramdisk but must then insure that any D/Ls done during the session are moved to a "real" disk before powering off the 130XE. K-65 does not provide a Copy command

as one of the (very handy) disk-handling commands currently supported. I must then exit back to DOS (DUP.SYS actually) in order to move the datasets from the virtual to the real disk.
K-65 provides an exit back to DOS thru the Exit or Quit commands and as you might guess, this part of the puzzle is being a little inconsistent as well.
- What is the approved/most successful/correct way to exit from a piece of object code back to DOS (2.0 / 2.5 / any other DOSs)?
- What is the difference between exiting from a piece of object code loaded as an AUTORUN.SYS file as opposed to the same code loaded by the "L"oad function of DUP.SYS? (For various DOSs, as above).

K-65 loaded as AUTORUN.SYS on DOS 2.0 exits normally. If I boot DOS 2.0 and then load K-65 or AUTORUN.SYS from the DUP.SYS menu, EVERYTHING works just fine until I attempt to return to DOS; then BOOM! I think John Dunning mentioned that K-65 simply attempts a RTS to return to DOS. He may have the luxury of being able to use a more structured DOS allowing a simple return such as this.
- Any comments?
- Anybody got any information on the DOSs mentioned or the use of this flavor of Ramdisk (other than what is mentioned in the standard Atari documentation)? If it is in an electronic form, tell me where or mail it to me!

Anyone who wishes to comment on any of these questions, feel free. If you send them to me, I can summarize to the list. If you can't reach me, send to the Digest. Any 130XE owners interested, let me know !

Thanks ahead of time!

"always make you words sweet because you dont know when you have to eat them ."
-I heard it somewhere on T.V.-

* GULP *

After 2 days looking,testing and using assempro, I have to say that :

- XREF/XDEF can be simulated by using SLABEL/ILABEL .
For example, a SMALL.LIB (small amiga.lib that can be found on one
of the fish disk) can be created using the same trick.
Assembling All the _lvo offsets and declaring them as SLABEL (XDEF)
and then using them using ILABEL (XREF) .
Advantage : takes less space on the disk (so a bigger work disk).
the assembling is faster. (the Offsets being pre-assembled.)

- Assempro even has an "online" help (you enter the rom call name or the
instruction op-code and it tells you what kind of arguments is needed).

- Assempro does not save the object code automatically to disk . (but if you
click on the QUIT option, it reminds you to do so). (I wonder what
would happen if there is not enough memory to hold assempro, the source code
and the object code .)

- The text editor is really primitive, I miss EMACS .However the search and
replace option is really powerfull (wich is proportionally complicated).

- Click to quickly on the window(creation/deletion) and you guru. (hell)
(The ONLY time I ever gurued using that prg)

- The demos are neat. (1 of each type, math, window,graphic etc...)

- The whole package is very compact, The only disk accesses being made are when
includes files are being used, directory/ssave/load/etc .. are being made.
jumping from the editor to the assembler or to other tools didnt seem to need
disk loading.

- Would I do it again ? (I mean buy the package ...) I think so .
The all in one package is really nice (and heavy to use at time.)
It was a pretty good deal for all the utilities furnished . (the debugger
seems really interesting, assembler,disassembler,reassembler,text editor,
all the libs, demos) .

- It has worked correctly on my 1meg amiga 500.
a ram: disk can really speed things up.

By the way ,What does Trap 14 do ?

Hmm... when _was_ this written?

Sure, Atari is big on vaporware,
but the abovementioned products are indeed out. The sx212 is the
1200 baud modem. You must buy a separate SIO cable for direct hookup
(about $6).
The 80-column adaptor is $80 and has been out for about a month.
It also can act as a printer buffer. So far, there is little soft-
ware for this. I think the name is the xep-80.
As for 80 col vt100 emulation, try KERMIT-65. It emulates 80 cols
in hires mode so you may need a monochrome monitor to see the display
(same for omniview). The only file transfer it supports is kermit.
KERMIT-65 is public domain (I think... or is it shareware).

I know Atari vaporware is one of the biggest jokes we Atarians(?) have to live with, but the SX212 is *not* one of them. I've seen them being sold at my local Federated stores, and a few of the local BBS users around the L.A. area have bought them for use with the 8-bit Ataris. I haven't had any direct experience with it, but it IS for $99, it IS Hayes-compatable (finding a good R: handler is the trick for using it with the 8-bits), and it IS a good bargain.

Just to throw some GOOD news around,
--R.J.

> - Any comments?

Yes. I've noticed that K65's behavior on "Quit" or "Exit" differs depending
on the DOS under which it is run. My most striking observation to date is
that behavior differs between OSS's "OS/A+" and "OS/XL" products - two nearly-
identical DOSes (sp?) which until now I had thought WERE identical. When run
under OS/XL, K65's quit/exit works as intended and you get back to DOS; under
OS/A+, the quit/exit command LOCKS UP the machine. The funny thing about this
is that I am running an 800, NOT an 800XL - and yet it is the "XL" DOS - the
"wrong one", which allows K65 to operate properly!

Why in the world the folks at OSS would change the linkage-back-to-DOS between
OS/A+ and the later OS/XL, I don't know, but that seems to be the case. I
also have a program or two that will run under OS/A+ but NOT under OS/XL -
kind of the "opposite" of the K65 situation.

Well, that's my two cents. Hope it was worth the 'vi' session to create it!

The Atari XEP80 80 column display for the 8 bit series has been shipping
commercially for a couple of months in the US. It does exist.

The XEP80 provides a monochrome 80 column display on a "typical" monochrome
monitor. It also provides a parallel printer port. It connects to the
8-bit computer line through one of the joystick ports.

I have more up-to-date information on this. It is true that the Atari
850 has not been made for some years (as I recall, Atari shut down the
850 production line when they started making XL computers or
thereabouts). However, there are supposedly still some 850s left here
and there. Look in the ads in one of the Atari magazines (that
include 8-bit info), and you are likely to see 850s advertised (as
least they were last year). ICD in Rockford, IL (I have their phone
number, but it's at home - sorry, try area code 815 long distance
directory assistance) makes (and sells directly if you want to buy
this way) the P:R: Connection (I may have 1 extra colon in that name).
Unlike the 850, the P:R Connection does not use any plug-in power
supply. It gets all the power it needs from the SIO bus (5V? I'm
not a h/w guy). I have heard that the P:R: Connection is almost
completely compatible with the 850, and I get the impression that one
does not necessarily _want_ to match the 850's characteristics exactly
(a somewhat "buggy" device. It works for me, though).

Again I have some updates to this. As I understand it, the Atari
XEP80 80-column add-on IS available, although I haven't looked for
one. I got tired of waiting (for _years_) and got CDY's OMNIVIEW

chip. It replaces the OS ROM chip, and provides, besides an 80-column
display (via the E: device as I recall), a "hybrid" OS that is
supposed to eliminate the need for a Translator Disk for running "old
400/800 s/w" that won't run on the XL's. (Actually, the last I saw it
advertised, OMNIVIEW is available for all major flavors of Atari 8-
bits, even 256K-upgraded XLs [Newell{?}-upgrade or compat., I
think]). Other features of OMNIVIEW include support for a RAMdisk
in 130XE or 256KXL machines (using "any DOS that doesn't hide itself
under the OS ROM"), and I believe it incorporates Newell's
FASTCHIP (sped-up floating point ROM code - speeds up BASIC etc.).

I never had the newer version of Chameleon that emulated a VT100, but
it doesn't matter (to me anyway). I used the "old" Chameleon (from
the defunct Atari Program Exchange) in ADM3A mode and didn't like the
80-column sideways-scrolling, so I hacked my own 40-col. adm3a40 into
termcap. Then I heard about OMNIVIEW. CDY sells for $10 (the last
time I got a new version) a VT100 emulator that uses the OMNIVIEW
chip. This program is called OmniCom. Also, there is a shareware
version of this program. OmniCom has nice features, like VT100
"keypad" (the "numeric pad") emulation, re-definable keys (single
char. code OR string), Kermit, XMODEM, ASCII capture (this doesn't
work properly for me though), and quick screen dump to P: (between
this and XMODEM, I get along well without ASCII capture anyway). I
currently have lost track of CDY (he either moved or [shudder] went
O.O.B.) so I can't give you a phone number/address. It was nice for a
while - he had a UNIX account down there, and I have "corresponded
with him" via e-mail as recently as last May (was it that recently?
here my memory really fails me?).

882. Globbo (Steve Jackson Games)

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-10 22:44:35 UTC
From: russell@puff.cs.wisc.edu
Message-ID: <1402@puff.cs.wisc.edu>
Source record: 117236
Cross-posted to: rec.games.board,rec.games.misc,rec.games.frp,rec.games.programmer,comp.sys.atari.8bit

I recently picked up a copy of Globbo by Allen Varney, published by Steve Jackson Games. It is an interesting game, but a pain to move the pieces around. I got to thinking that a computer version would be a good idea.

Does a computer version exist out there? Since I don't have a permanent account on any UNIX system, it would have to be something I could type out for my Atari 800 XL (BASIC). I could maybe translate from other machines if I knew how their graphics etc worked, and I could probably also change from Pascal or Fortran (graphics?) if I had to (again, with help). If there is a public domain version, would somebody please email me a copy.

If nothing exists, perhaps some bright programmer with alot of free time could write it up for me and send it my way. Unfortunately, I'm not sure how legal this is (this is why I posted to rec.games.frp--I heard people from SJG read that group--if so, would this be all right?). I purchased the game and I don't intend to sell any copies of anything, but I'm not a law student. What applies here?

Thanks in advance for your brilliant replies! :-)

Globbo????? What's Globbo???

Also, Does any other implementation of Car Wars exist, other than Auto Duel,
by Origin Systems??? (Auto Duel is pretty sad if ya ask me. You can WIN!!
Also, it sadly misses many higher features of Car Wars.)

The following article was contained in Ron Kovacs' national Zmagazine,
Issue 91 (latest, I think). I am reproducing it in its entirety without
comment, so you can draw your own conclusions. I know at least one
person here on the net has mixed feelings about ICD, but I think as a
whole, they have been good for Atari owners (esp. 8bit owners).

==========
ZMAGAZINE NEWSWIRE
==========

DATELINE: 1-27-88

GOOD NEWS FOR ATARI OWNERS!

ICD, Inc. and OSS, Inc. (Optimized Systems Software) have just signed an
agreement which will "add new life to all Atari computers". Under this
agreement, ICD will add the manufacture, marketing, and support of
all current OSS software titles for Atari computers to ICD's already
powerful Atari product line.

ICD's friendly, helpful staff is now trained in all aspects of support for
the complete OSS product line including:

MAC/65
MAC/65 Toolkit
ACTION!

ACTION! Toolkit
BASIC XL
BASIC XL Toolkit
BASIC XE
Writer's Tool
DOS XL
Personal PASCAL for the Atari ST

Ordering and support for ICD/OSS products are available by calling 815/968-2228 from 8AM to 5PM CST Monday through Friday. Support is also available 24 hours a day 7 days a week on the following Electronic Bulletin Boards:

ICD/OSS BBS 815/968-2229 300-9600 baud, CompuServe,GEnie, Delphi, and BIX. ICD's 24 hour FAX is connected to 815/968-6888.

The San Jose, CA numbers for OSS will no longer be providing support. Orders for OSS products may be placed now. All products will be shipping in quantities soon. For more information call any of our product support lines or write to:

ICD/OSS

Yes, the SX212 is definitely not VaporWare.....I just got one today and am typing this message via it and Chameleon. It's your standard Hayes-type modem, but at a much nicer price than most - I got it for $87 from Computer Mail Order (1-800-233-8950). Be forwarned though... although you *can* just plug it right into your 8-bit via the SIO port, finding software to work that way is *extremely* difficult at this point in time. My advice therefore would be to do what I did - order a PR Connection while your at it for $59, and a RS232 cable (25 pin male D-sub to 9 pin male D-sub) for $12. Then you'll be able to use a wide range of software...Express (my favorite for Atari BBS's), VT100, Amodem, Chameleon (works great with my schools Unix system), and more.

-Ray

888. The Atari XEP80, my experiences with it.

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-13 14:51:56 UTC
From: larryw@dasys1.UUCP
Message-ID: <2968@dasys1.UUCP>

```
---------------------------------------
Using the Atari XEP80 - Winston Lawrence
---------------------------------------
The XEP80 card has finally made the transition from vaporware to
hardware this is a review of my experiences with the adapter box in
response to several queries that have been posted here. The XEP80
gives all 8-bit Atari systems a true 80 column by 25 row visible
screen. I say visible because the device internally can handle rows
that are 255 characters wide, with an 80 character display window.
.
The unit, about the same dimensions as a Hayes smartmodem, connects
to joystick port one or two and to a monochrome monitor. All connecting
cables and a power supply are included with the unit. Forget about
using a color tv or color monitor as a display device. The display is
legible on a black and white tv it is just not very good quality. I
tried the unit on a Panasonic color tv (with seperate video input ), a
sony black and white tv, a black and white Panasonic cctv monitor (my
normal display device for several years - up until a few weeks ago),
and on a Magnavox BMC-80 monochrome (amber) monitor. The normal (40)
column display fills the screen on both the Sony black and White TV
and the Panasonic (cctv) monitor. The BMC-80 displays an amber box in
the center of the screen with almost two inches of black border on all
sides with the normal Atari display.
.
Okay As I said before, scratch the color output, the display was
unreadable, which was as I expected. The Sony black and white TV and
the CCTV monitor both gave 80-column images (sort of) with the CCTV
picture being a little sharper. I say sort of because I seemed to be
missing around the first 10 characters or so of every line.
.
SLOW BURN - after all I paid for an 80 column display not 70 columns
with an invisible 10 character window right.
.
CALM DOWN - on went the BMC. Fantastic. The screen FILLED up. No more
two inch black borders. I got sharp legible 80 characters all visible.
I had expected this to be the best display as even with the 80-column
emulators (KERMIT, VT100) the BMC-80 gave the sharpest images.
.
Okay so what was wrong with my other displays? Well, it seems that
some tvs (and even monitors apparently) have a problem with a thing
called overscan, wherein they do not display the first few scan lines.
A normal 40 column Antic display takes this into consideration by not
using the first few scan lines, so my 'old' displays never saw
anything wrong.
```

.
Guess what. The XEP80 writes to each and every scan line, in its
entirety so if your tv/monitor doesn't display them, you won't see
80 columns either. If you are going to buy an XEP80, make sure that
you have a good monochrome monitor - NOT a TV.
.
The XEP80 comes with all the software needed to get you 80 columns,
and continuing the 8-bit tradition (thank you VERY much Atari)
SOURCE CODE for the XEP80 driver/handler and several useful BASIC programs
that demonstrate windowing, blinking characters, graphics e.t.c.
VERY NICE.
.
The software acid tests
=======================
Most sophisticated 8-bit software fails with the XEP80 as will most
(if not all copy-protected software). The XEP80 relies on its handler
being present in order to drive the hardware. Most copy protected
software comes on a disk with its own DOS and will either not allow an
'outside autorun type' handler to be loaded, or will wipe out said
handler because it uses ram based on its (the software applications)
view of memory and will wipe out the XEP80 handler even if it could
be loaded. Software that wrings every byte out of the normal 48K or so
of ram available to it, will ALSO fail because the XEP80 handler will
need a little under 2K of this for itself.
.
In general, any software that uses/modifies the display list or
writes directly to video ram or uses graphics modes other than zero
will fail. The XEP80 can be switched between 80-column and standard
display modes but you have to be careful about where you load the
handler so that it is not overwritten by graphics (mode) changes.
The XEP80 only intercepts calls to the E: S: and P: handlers (which it
replaces) if they use the handlers (via CIO and the IOCB calls). Most
'sophisticated' 8-bit software uses the display list and/or video ram
to provide good visual images and so fail.
.
Instead of just saying tough we blew it, the XEP80 documentation refers
to these display list calls as 'illegal calls' a minor but annoying
point as display list programming is one of the things that made the
8-bit Ataris the powerful (for the price) graphics machines they are.
.
BASIC works (just don't position the cursor into the non-scrolling 25th
row). All the DOS versions that I tried worked (MYDOS, DOS 2.0, OS/A+).
The assembler editor cartridge worked. MAC65 worked (an older disk
version - I don't have the cartridge version of MAC/65). My ACTION
cartridge failed, but then again my ACTION cartridge doesn't always load
properly anyway (I think I have a bad EPROM or something).
Deep Blue 'C' sort of works, after doing *any* compilation the system
'locks up' I think because it is overwriting the ram where the
XEP80-handler lives. The same thing happened with the 'cc8' compiler
posted on Usenet a while back. The actual 'C' programs work just fine

providing they do not 'violate' the display limitations mentioned before, and the 'C-linker' works in 80-columns without locking up the system. All of this was tried with an 800 and 800Xl with and without an ATR8000 expansion unit attached.
.
What else fails? Every comm program that I have failed. AMODEM, BBS EXPRESS, CHAMELEON, KERMIT-65, JTERM. I did not try the TELINK cartridge but then who would care if it worked anyway (no file capture or transfer capabilities in TELINK at all). Every word processor that I have fails; The Atari Word Processor (real-old predecessor to the Atariwriter); text-wizard; letter-perfect; Atariwriter; Word Magic; MEDIT; speedscript; all failed. I do have a REAL old BASIC MINI-WORD processor (a pd program) but like TELINK its a kludge, very bad so who cares if it works anyway. GAMES? a couple of text only adventure games worked, but were formatted for 40-columns anyway. Otherwise if they use Player-Missile-Graphics, Display list Modifications, direct screen writes (all the standard stuff that gives our 8-bit programs some flash) are all going to fail in 80 Columns.
.
I should qualify the term fail here. You DO NOT lose your normal Atari screen capabilities. Fail means that you see nothing at best, or the system locks up when you have the XEP80 loaded. I have a Y switch that lets me switch the ouput between the XEP80 cable and the normal Atari output cable. By moving the switch I can get 80-column or the standard display, on the one monitor. A real nice future hack would be to have the switch go to two monitors and have them active simultaneously. The XEP80 buffers its own screen ram so the hardware as far as I can tell could let you have TWO different displays running concurrently. A program running on one and a trace of the code on another screen. (Bug65 does that now with the other 'screen' being a printer). The XEP80 also gives you eight, yes eight printer handlers (P1:(P:) through P8:) P1: is the printer port built into the XEP80 (yes built into the XEP80). P2: e.t.c are whatever other printer ports your hardware/dos can support. I have three now, One in the XEP80, one in my 850 interface and one in my ATR8000.
Unfortunately I only have one printer.
.
Lest this sound too negative at this point. I DO LIKE THE XEP80. I bought it for telecommunications; program development; and word processing. I am writing a comm program in 'C' to use the XEP80. I hear that Atariwriter-80 is out (although I can't find anyone who actually has it for sale yet) and that will handle my program development/word processing needs when I get my hands on it. I am sure that others out there are busily adapting/writing new stuff to use this device.
.
One last benefit to the XEP80. Programs that can use the XEP80 also run faster, in some cases 50-75% faster. A listing to the XEP80 screen screams by. Keep your finger CLOSE to CTRL-1 if you want to actually read what you are displaying. Why? because the ANTIC

chip that used to handle the screen I/O is turned OFF by the XEP80
handler and the 6502 is not being constantly interrupted. A couple
of BASIC timing loops that I tested while printing to the screen in
a FOR-NEXT loop, ran almost 150% faster. I attribute this to the fact
that the BASIC interpreter was able to do its thing MUCH faster when
ANTIC wasn't stealing the 6502 CPU cycles.
.
I think this is enough for now - I hope that I have gotten my point
across. The XEP80 does exist and I like it. If you do some programming
and have a decent monitor you probably will too. If you are a heavy
Comm user, wait for the software to start flowing then buy the XEP80
-or- better yet take charge, write some software yourself and buy the
box now. If you DON'T have a decent monitor then you have to consider
whether the $200-$250.00 that it will cost you to upgrade your monitor,
buy the XEP80, and get a decent word-processor is cost effective to you.

> order a PR Connection while your at it for $59, and a RS232 cable
> (25 pin male D-sub to 9 pin male D-sub) for $12.

My system includes an 850 Interface -- from what you say here, and earlier
postings describing the PR Connection as "...almost completely identical to
the 850..." etc., it SOUNDS as though I should be able to use the SX212 with
what I already have: I've got everything right down to the 25-pin male D-sub
connector-- would an SX212 operate properly when plugged into the 25-pin end
of the cable connected to port #1 of the 850? I.e., this is where I plug my
off-the-shelf 300-baud modem in today...

Thanks in advance for info.

890. Linking two computers

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-14 00:38:25 UTC
From: NU109703@NDSUVM1.BITNET
Message-ID: <578NU109703@NDSUVM1>
Source record: 117244

I would like to be able to hook up two atari computers for interactive games, etc. that require that you do not see the screen of the other person.

My brother and I both have Atari 800XL's with parallel ports. I was wondering if I could buy a parallel-to-parallel cord to use for data transmissions, (for a game of battleship, for example).

If I could, then I want to write an interrupt routine for data tranmissions. This, as you probably can see, is not necessary for a game like battleship, but it would be great for some type of space or fast moving game. That way you would not have to write special programs for two displays, you could write a program in which the inputs would be from:
(1) You - your keyboard and joystick inputs.
(2) Other person - parallel interface inputs.

A program could then give a "personal" feel. You would always be the #1 player, the subject of all attention. Also, a program would not be written for awkward sharing of the keyboard.

It may be difficult to decode the interface inputs, but I'm ready to sacrifice a little work to get some type of interactive but still two separate user system.

Can I do it?
If I could, I would probably send in the results to a magazine like Antic or Compute (I'd like to get some money for it) and then I would write some programs for it. I have knowledge of machine language, VBI's and DLI's. I have the technical reference manual, but I find it hard to understand sometimes, especially I/O, since I really don't have the time for it. I am hoping for a Co-op job this spring and summer, so I'll be in the position that I want to be: working with computers, but still free enough to use my time as I want to (No finals).

If the magazine accepts my ideas, I would then write programs that use the two computers hooked up and possibly send them in.

I have never used the parallel interface before, so I don't know if it is bidirectional or not. If it is not, I could use the status lines and hope I could figure a way to decode and encode them. (I.E. signals for data, quit data, start data, ready to read or write, etc.)
Using the printer lines would also make it possible to use the disk drive normally and store program results. It would consist of a mutual agreement between the programs that no data will be transferred and when the disk operation is done, data may be tranferred again, possibly accomplished by some internal flag that the interrupt routine works on. This could provide some SPECTACULAR computer-vs-computer games with a very

fast interrupt routine and some randomization in the programs.

Sorry, if I have gotten on an arctangent, but I think this would be a good idea, even if difficult to implement. But I think after it is implemented, this could be used simply by building on a basic framework for a program to be written.

891. communications on an Atari 800

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-14 01:59:01 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8802140159.AA02457@mitre-bedford.ARPA>
Source record: 117245

As usual, the net subscribers have provided a good survey of the available options. My comments don't add much, but maybe will help to confirm some of the impressions you have received from other mailings.

The 800 can be used as a vt100 terminal quite successfully. The Atari 850 interface and the ICD P:R:Connection are the most widely accepted choices for interfacing to an RS-232C device. The serial bus in the Atari is a TTL bus, so needs TTL to RS-232C level converters to run a normal modem. Also, the "handshake" signals would be absent, but you could do a trick like using the cassette motor control line to signal DTR or something. There is a device called the R:Verter that used the serial bus in this way. I don't know if it is available any more. The 850 is hard to find. This leaves the P:R:Connection as the best choice, unless you want to hack together an interface or buy one of the Atari modems with built-in interface.

As for terminal emulators, the clear choice, given your requirements, is CDY's OmniCom. This does a pretty good vt100 emulation (the adjective "halfhearted" that someone used doesn't seem to me to be justified -- it handles the graphics and cursor commands from my screen editor just fine), and also supports kermit, xmodem, and ascii transfer. Ascii transfer can go to a file or to the printer if you wish. Also there is an instantaneous "print screen" function that is very handy.

John Dunning's kermit65 is a very good choice for vt100 emulation, but at last report lacked some of the features you specifically mentioned. It also lacks macro key definitions, and so far as I know this means you have to do any keypad operations as sequences of three or so keystrokes. Dunning will, I am sure, fix all this one of these days, but right now OmniCom is really what you need. It's available as a "shareware" program, which means copies of it are available free, but the author requests a contribution if you wish to keep on using it permanently. I have a copy which I'll be glad to send if you wish.

From: CCSCHR%UWOCC1.UWO.CDN@forsythe.stanford.edu

[...]
DOS 2.5 when booted will always load the 850 interface if it finds this
device powered on. This happens just after the Ramdisk is initialized.
I then load K-65 from the DUP.SYS menu and K-65 has problems with what
DOS 2.5 has done to the 850, claiming the "850 is not responding".

That's not a problem. What that message really should say is something
like "I tried to load the driver, but couldn't. Maybe it's already
loaded?" In your case that's what's happening; it's already there, so
when Kermit-65 tries to load it again, the 850 tells it to shut up.

My circumvention is to turn off the 850 while DOS 2.5 is loading and
then power it back up before loading K-65. This works fine but is
clumsy as hell and will definitely shorten the life of my 850!!!

You don't need to do that. It's completely harmless to let Kermit try
to load the driver again.

So at this point, I can get the data to the Ramdisk but must then insure
that any D/Ls done during the session are moved to a "real" disk
before powering off the 130XE. K-65 does not provide a Copy command
as one of the (very handy) disk-handling commands currently supported.
I must then exit back to DOS (DUP.SYS actually) in order to move the
datasets from the virtual to the real disk.
K-65 provides an exit back to DOS thru the Exit or Quit commands and as
you might guess, this part of the puzzle is being a little inconsistent
as well.
- What is the approved/most successful/correct way to exit from a piece
of object code back to DOS (2.0 / 2.5 / any other DOSs)?

I believe I've asked the net about this before, and never gotten a
definitive answer. Kermit-65 exits by doing an RTS. That works with
DOS XL, and apparently some other things as well, but not everything.

- What is the difference between exiting from a piece of object code
loaded as an AUTORUN.SYS file as opposed to the same code loaded by
the "L"oad function of DUP.SYS? (For various DOSs, as above).

As far as I know, none. Anyone know better?

894. c compilers?

> that oss had "tiny c" at one time. How extensive are the libraries
> with these compilers? Any help appreciated.
>
> Roger Cornelius

About the C compilers. There is a public domain version of C for
the 8-bit Atari. It is known as Ace C. It is an upgrade of Deep Blue
C that got put into the public domain (ie. It is ***FREE!!!***) If
there is enough requests for a re-posting then I am sure it will get
re-posted. If there is only two or three people then a direct mailing
might be in order. Let your desires be known and I'll see what I can
do.

900. how to add 256k to my 800XL

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-18 20:32:24 UTC
From: steve@tic.UUCP
Message-ID: <174@tic.UUCP>
Source record: 117254

I am posting this for a friend please send all replies to:

..!ihnp4!alberta!edson!tic!tac!amunds

Thank you...

I understand that the atari 800XL can be upgraded to 256K by
replacing the 64K chips and doing some appropriate address decoding
with the ACIA. I was wondering if anybody could direct me to an
appropriate source to find the nescessary information or tell me what
is required. I am a 4th year computer engineering student so technical
descriptions would be just fine.

Thank you
Dave Amundson

> (for a game of battleships, for example).

I sent a solution to a similar problem to someone on the bit-net quite awhile ago. This time I guess I will make it public (perhaps there are others out there who are interested).

Although this solution isn't exactly what you asked for (I have no info on Atari XL parallel ports [unless of course you're referring to the expansion slot on the back]) it may be useful to you.

The joystick ports on the Atari 8-bits can be configured for output as well as for input. This will rule out joysticks (except on the old 400/800s) but will allow you to communicate between your computers.

STEP #1 - THE HARDWARE
This is the easy part. All you need are two joystick extension cords and two nine-pin joystick plugs, all available at your local Radio Shack. Cut the cords at the end in which you would normally plug your joystick (not the end which plugs into the computer) and strip the green, yellow, orange, red and grey wires enough so you will be able to solder them onto the plugs. The other wires are not needed so you might want to cut them a little shorter just to keep them out of the way. Solder both cords as shown below:

PIN JACK 1 JACK 2 WIRE

1 data 0 data 4 Green
2 data 1 data 5 Yellow
3 data 2 data 6 Orange
4 data 3 data 7 Red
8 ground ground Grey

To test the interface, plug it into both computers (the one in port 1 of one computer should also be in port 1 of the other computer), turn them on and try the following test: On one computer type POKE 54018,56:POKE 54016,0: POKE 54018,60:FOR N=0 TO 0 STEP 0:? PEEK(54016):NEXT N. On the other computer type POKE 54018,56:POKE 54016,255:POKE 54018,60. Now, still on the second computer POKE 54016 with any value from 0 to 255 and the same value should appear on the screen of the first computer. If not, something has been done wrong (check your wiring).

STEP #2 - THE SOFTWARE

In order to make practical use of the interface, you need to write a driver. Following is one that I have written (WARNING! This is a BARE-BONES driver with ALMOST NO error checking! You will want to spruce things up a bit before you trust it with anything substantial.)

The program will install the driver in memory and then change LOMEM in order to protect it. This wastes all the memory between the initial position of LOMEM and the start of the program so you will want to change things (ie. make it relocatable and automatically loading above LOMEM) to overcome this. [Note that my program was written a couple of years ago as an experiment - it was never intended to be a comprehensive driver - still, it does illustrate the basics of what is required in a driver.]

Once the driver is installed properly, you can communicate between the two computers using the normal OPEN,CLOSE,PUT,GET,READ,etc. commands specifying the 'X:' device. I have tested this in BASIC but have not had a chance to do so with C or Action! (I no longer have two Ataris). It should, however, work with any program or language which sticks to Ataris standard I/O procedures.

For more information see _Mapping_the_Atari_.

> wondering if I could buy a parallel-to-parallel cord to use for data
> transmissions, (for a game of battleship, for example).
Just what port are you referring to by "parallel port"? Do you have an 850 interface with Centronics printer port or are you referring to the joystick ports or to the 50-pin bus connector on the back of the 800XL?
Actually, in only one of these cases is there much hope of doing what you ask with just a "cord". That is the case of the joystick ports. I think you could in fact wire them up with a simple cord and then program them to talk back and forth. Of course then you would have no place to plug in the joysticks, so you would wind up having to do something more complicated than just a "cord".

I don't think there is any way to program the Centronics ports to accept inputs, so the 850 approach would require using a serial port at each 850, which actually is another possibility.

The 50-pin parallel bus connector on the back of the 800XL is hardly a "parallel port". If you tied two of these together, I think all that would happen is both computers would crash because their address lines would conflict. You could do almost anything your heart desires with this "port" but you would have to design an interface from the internal CPU bus (which is what is on this connector) to the external gadget. I.e. it's not a question of a "cord".

> I have knowledge of machine language, VBI's and DLI's. I have the
> technical reference manual, but I find it hard to understand sometimes,
> especially I/O, since I really don't have the time for it. I am hoping
> for a Co-op job this spring and summer, so I'll be in the position that I

> as I want to (No finals).
I would hate to discourage you from undertaking your project, but from the tone of your question I get the impression that you may not have much idea of how much hardware design is involved. Tackling the project would undoubtedly teach you a lot about computers, but don't underestimate the effort involved.

And, finally, a comment that I wish I could go back and tell myself when I was your age: Don't think you will have more time to do this project at any future time in your life. You almost certainly WILL NOT. You will just get busier and busier, at least until you retire at age 65. The best thing you could possibly do with your life is to BELIEVE THESE WORDS, think about

their implications, and then figure out how to take this awful news into account in planning how to live your life right now. More likely, you will think I am being silly and will only realize the truth of what I have said when you are about 40 or 50. Good luck, either way.

By the way, this past week has been the busiest of my life.
Here's how it goes: Start working on my class project at 8:00 PM
Work on it for, say, 16 Hours, Go to class for another 3 hours,
Go to sleep for 5 hours (By the way, I have eaten supper at the normal
time only about once in the past week). Yesterday, I ate nothing.
Then repeat this process for 6 days straight. Keep in mind that
this was a horribly confusing process. We (team of 2) were working
on a simulator of a M6800 Chip, with a simulator portion and a microcode
portion, which was supposed to take about 6 weeks. He had the microcode
portion, and I had the fortran simulator to do. His microcode project
was not written very well, so I took it over and wrote the entire
microcode in 4 days. Well, you know that it's very hard to keep track
of, and I'll have to take the course over again next year, but at least
I'll know *exactly* what the course is about, and should get an A or B.
-- Consider my present situation first.

> So how many joystick ports are there? My 800/Fossil has four. Is there
> only one on an XL?

There are two joystick ports on the XL/XE series machines. I guess I was thinking that both would be used to provide an 8-bit-wide parallel port such as the fellow referred to, since each has just 4 parallel bits.

You could, of course, use just one joystick port to get a 4-bit parallel path, leaving the other port free for a normal joystick. I believe the individual pins can be programmed for input or output separately, so you could even set it up with two 1-bit inputs and 2 1-bit outputs. Hmm... this would let you implement two separate bidirectional serial ports. In turn this would let you set up a RING of serial ports with as many Ataris around the ring as you wished. Or you could set up two independent unidirectional rings. I can see there are a lot of communication possibilities I never even thought of, using the joystick ports.

However, if you want to do an 8-bit parallel connection there, it would tie up both ports as I indicated previously.

In reference to Fred Sullivan's query, the 800XL has TWO joystick ports; the discussion that claims "but then you wouldn't be able to plug in your joy-stick" assumes (quite natrally) that one wishes to perform 8-bit I/O -- and it happens that each joystick port accesses FOUR bits. Therefore you need TWO joystick ports to transmit ONE 8-bit data byte.

Or do you?

I would give some thought to the possibility of using only ONE joystick port, and performing 4-bit I/O over the port-to-port line, reassembling the original bytes after both halves ("nybbles") are received. This may sound awful, but remember something else: SERIAL data transmission uses a ONE-bit data line, and that works just fine! (You could conceivably use the four-bit joystick-cord connection to send four simultaneous channels of serial data, by the way.... It is entirely a matter of how complicated a handler you're willing to attempt to write!

Now you've got me wishing I had a second Atari to try all of this out on!

:-)

>(I guess they think we're only interested in games :-)

I did something similar about two years ago too. (However, it was Antic that turned me down then)

I wrote a two player Adventure game in standard Atari Basic. The second player was attached through a serial port to another Atari or terminal. It also worked with the then popular MPP 300 baud modem drivers that talked at 300 baud through a single joystick port. I made a simple "null modem" cable that allowed the two Atari's to talk at 300 baud without any modem hardware. (just two Radio Shack replacement joystick cables)

The adventure game wasn't much. I wrote it to prove the concept worked, and work it did. The game generated a random 20 room maze and allowed the two users to wander around the maze picking up treasure and talking to each other.

My favorite part was the descriptions about distance when someone talked. (ie. You here a voice in the say:) Also playing a standard type boring adventure game really changed when the description: "Another adventurer just entered the room" appeared on your screen.

I wish Antic would have been interested. I kept dreaming about writing "REAL" games in ACTION using the same hardware configuration.

910. Programming the Trak-Ball

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-22 15:37:26 UTC
From: lackey@Alliant.COM
Message-ID: <1257@alliant.Alliant.COM>
Source record: 117114

I just picked up one of the Atari Trak-Ball controllers, and after using it for only a few hours, think it is great for some games, and not so great for others.

It has a switch on its side. One position is marked "joystick" and the other is marked "trak-ball". In the joystick position, it can be used in any game that uses a joystick, and simulates trak-ball behavior. It works well in games where the joystick position is "integrated" to program the position of the player (the target in Missle Command, the human in Berserk, etc). In other situations such a Pac-Man or Battlezone, the trak-ball actually makes things more difficult.

To use it in trak-ball mode, the game must be programmed for it. Home computer (as opposed to 2600) Missle Command has trak-ball mode, which you enter by typing control-T. This allows you to get much better control, and handling is much like the real arcade game.

My question is, how do you program to the thing? It looks like it is one of those things where rate of motion in one direction is determined by phasing of two changing signals, and a driver counts transitions. Does anyone know for sure? All I've done up to now is write a little Basic program to dump its output to the screen, and have noticed behavior suggesting that above.

Note: The trak-ball is not usable in paddle games. Too bad.

Anyway, for $9.00, the trak-ball is well worth it.

Disclaimer: Do I have an opinion yet?

911. Re: how to add 256k to my 800XL

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-22 17:30:35 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8802221730.AA05207@mitre-bedford.ARPA>
Source record: 117115

You can indeed upgrade your Atari 800XL to 256K quite easily, i.e. by replacing the 64K chips with 256K ones. The 64K chips have 8 address pins which are multiplexed 2:1 to give effectively 16 address bits, which figures out to 64K of address space. The 256K chips need effectively 18 address bits, or 9 pins if multiplexing is done in the same way as for the 64K chips. The bottom line is, the 256K chips have one extra pin that must be controlled.

If you just change the chips to 256K chips, that extra pin will be held at a logic "1" by a 3K pullup resistor near the corner of the board. So the machine will still work normally but will only utilize 1/4 of the 256K chip address space.

To get at the rest of it, you need to build a simple logic circuit that figures out when to yank down on that line and select one of the other 64K regions. The logic needed is fairly tricky because there are two clock phases, corresponding to the multiplexing of the address lines; there is also the issue of whether the CPU or ANTIC chip is requesting access; and finally, the logic has to take into account the program's commands for which section of memory to access. In the 130XE, and therefore in most 800XL upgrades, this information is represented by controlling previously-unused bits in the "Port B" PIA register at $D301 or decimal 54017. Even though there are 6 or 7 logic conditions to consider in calculating the correct bit value for "Address Bit 9", by using multiplexors to implement combinatorial logic functions it is possible to do the job in about 7 or 8 chips.

The details of memory bank selection in the 130XE are described in the most recent version of "Mapping The Atari", and you should familiarize yourself with this scheme (basically the bit definitions at $D301) before attempting to design a compatible board.

Several commercial companies have built such boards. I have been using the board from Newell Industries, the so-called 256KXL "Newell Board". I was disappointed to find that this board departed from 130XE compatibility more than I thought was necessary, so I reconstructed the schematic and made a design modification so that it would do a more nearly perfect job of emulating the 130XE. I can supply you with the original and revised schematics if you wish. Being an engineering student, you should probably build your own board, but it might help to have the Newell schematic and the design information I used to modify it. Or, you could buy a Newell board and consider making the patch to it that I worked out. Also, there have been a few magazine articles on how to design such a board in recent years.

If you want to order from Newell, his address/phone number are:

Newell Industries
602 E. Highway 78
Wylie, TX 75098

(214) 442-6612.

Usually Wes Newell himself is available for technical questions. By the way, he is also handling sales of the CDY "OMNIVIEW" 80-column upgrade chip, which I strongly recommend getting if you plan to do a lot of word processing on the 800XL. (An 80-column word processor program comes with it.)

You will also need software to make the expanded memory do you any good. One of the most useful things to do with it is to run a RAMdisk. If you buy or build a standard Newell board, you may be interested to know that OMNIVIEW256 includes a RAMdisk program which is ROM-resident, i.e. available by a couple of keystrokes. The word processor that comes with OMNIVIEW also lets you take advantage of the extra memory to set up a really BIG text buffer. For example, I routinely run an 80K text buffer simultaneously with a full-sized SS/SD RAMdisk. This lets me write almost 25 pages of text before I have to save to disk! Also, saving to RAMdisk is very fast.

If you'd like a copy of the design info for the modified Newell board, send me a mailing address and I'll mail you a copy.

I know what you mean about just getting busier and busier! And I am only 32! I can think of many projects that I would LOVE to do with my Atari(s) (800XL and 130XEO [O for Omniview]), but I JUST DON'T HAVE TIME ANYMORE! There are too many other things that I also like to do, and that are equally important to me; not the least of which include social activities, and keeping up with maintenance, repairs, and even "enhancements" of/to my house. (A house can consume time like nothing else, except maybe children; the latter my wife and I had little interest in before, and NO TIME now!)

Someone mentioned wanting to use the 8-bit Ataris to control various "household" devices. I have never tried this, but if I were going to, I would study the columns, articles, etc. in ANALOG, ANTIC, etc. magazines. In particular, I like to read the "Nuts and Bolts" column in ANALOG and dream. In fact, before I found a used Koala pad (I REALLY WANTED one BADLY!), I was considering building a gadget described in that column (issue #/month escapes me just now) that emulates the Koala Pad (but may need an extra button to do this with MicroIllustrator). The device was named the "Rodent" and used a R-Shack type joystick pot (a joystick "innards" with 2 variable resistors at right angles, for you "software only" types. :-) I should talk... I fried a 130XE! ouch!). I want to try to write my own flight simulator someday, just for gliders (sailplanes), and a relatively simple one (little if any recognizable scenery, no fancy instruments, etc.). The "Rodent" would be a great stick for such a "bird." Now, what to use for rudder pedals? ...

Remember, a mouse is just an upside-down trackball with a tiny ball, where the mouse pad (table) is your hand... (essentially). Input devices are fun to play with (even if only in your head).

As time goes by, I find myself USING my Atari(s) more, but having less and less time to "hack" (program for fun and learning how the Atari's innards work; I have never even tried P/M graphics yet - and I have ACTION! and the Prog. Aid [old version of Toolkit] disk, so I have no excuse like "I don't want to bother to learn 6502 assembler...[which I don't, at least for the time being!]).

So, I sincerely wish any and all "hobbyist hackers" the best of luck, fun, and so on with their Ataris. (And if this article is too verbose/long for anyone, please accept my humble apologies. Sometimes it seems to me that I was born with a hard-coded dash-v option!)

>Chris Chiesa

Here's a method I have used a lot and it works well: Rather than trying to assemble the nybbles (a hard thing to do really, if you sit down and think about it) -- use an 8-bit shift register (serial-to-parallel). You use one line of the joystick port to clock the shift register and another line to set the ones/zeros on the data input of the shift register.

Why do it this way? Well, companies like MPP have developed nifty little ways of generating a certain baud rate by timing loops and tying down the CPU (more than it is already by the screen). With the shift register, you can clock the data out at any rate you feel like, whenever you can get it out.

I used this on an old Commodore PET (the original 8K one with the chicklet keyboard) to set-up a modem interface. I used the shift-register idea to take full advantage of the 8-bit parallel port that the PET had (the only one at that!). I sent data to an 8251 UART chip which had a baud-rate generator IC built into it. I was able to use the board successfully at 1200 baud with no problem, and I'm sure I could do better if I had the opportunity.

It may be the SX212 that I have found in the stores up here. It has
both an RS232 and an Atari 800-type SIO connectors. Looks pretty
tempting...
The price is $179 CDN, which usually indicates the price in the
US is about $90 US.
Is it true that it comes with NO R: handler?? That is almost,
but not quite, unbelievable.

Please, if we must post a C compiler, lets post the best, CC8 by Steve Kennedy. Steve, if you have updated it at all or plan to in the near future, add your two cents worth here. No use in posting Ace C for new users. Of course, you will still need all the linkers, etc that usually come on the Ace C PD disk, since CC8 is just the compiler.

From: lazear@gateway.mitre.ORG
Message-ID: <8802241428.AA07685@saturn.mitre.org>
Source record: 117129

(I tried replying directly to Dennis, but have to resort to the list...sorry)

Dennis,
I am interested in your Ramcard.
I have an old 800 and am concerned about the card
working with existing software (DOS 2.0 and binary stuff). How does
one add the proper driver to DOS (does every disk need AUTORUN.SYS
with this driver?) and what about binary programs that are on
boot disks? Do you have to have all the programs you want in the
ramdisk on your boot disk (or what is the procedure to load the
ramdisk?) or is it battery backed up, so when you turn off the 800
the ramdisk is non-volatile?

As you can see, I am not well versed in the ram extensions to the 800,
but your price and apparent simplicity would add dynamite to my system.
Thanks in advance for any answers.

Walt (Lazear@MITRE.Arpa)

2/24/88

Subject: Linking and controlling with Atari computers

1. Linking two computers through the 850 RS-232 ports is the most common technique. The running of Battleship games is a natural for link. Any of the common modem programs are used to provide the control link. When using the RS-232 ports connected directly, it will be necessary to interchange two leads (the name of the leads escape me at the moment) so that the two machines will operate (receive/transmit) alternately instead of simultaneously. The concept is exactly the same as using two modems through a phone line as far as the computers are concerned.

2. Controlling things with the Atari computer through the game ports is limited only by ones imagination. The ports support both I/O operations, and hardware wise, it is only necessary to buffer the signals to prevent excessive loading on the driver chips and internal power
of digital I/O, and one analog input sense only. Two ports will double the bits, etc. A driver program will have to be tailored for the control actions (I/O) desired. As an example, the Atari works great as a weather station monitor where the digital I/O is used for wind direction position indicating, and the analog input is used for wind speed and/or temperature input.

Happy computing,

Hugh Wells

OK. I have a 65XE, with a round connector on the back to connect to a monitor.
Up to now, I have been using the standard modulated output, connected to a
regular TV.
I just got a nicer TV that has direct video and audio inputs.
I assume that going from the 65XE directly to the TV's video input will give
me a sharper picture, and *maybe* allow GRAPHICS 8/80 chars to happen.
So...
Does the 65XE video port supply composite video and direct audio out?
If so, does the Reticon cable I have seen that terminates in two phono jacks
work for me? If so, how is it connected? I would rather not just try it,
given the $'s I paid for the TV.

In article <1257@alliant.Alliant.COM>, lackey@Alliant.COM (Stan Lackey) writes:
> My question is, how do you program to the thing? It looks like it is one of
> those things where rate of motion in one direction is determined by phasing
> of two changing signals, and a driver counts transitions.

That is correct. The joystick "switch" inputs are used in pairs to provide a "direction" and a "velocity" signal for each axis. The bit positions in PORTA are:
XDIR = $01 YDIR = $04
XMOT = $02 YMOT = $08

The best way to monitor the trak-ball is to set up a periodic timer interrupt service routine that compares the ?MOT bits with those from the previous sample. If either of them has changed since the previous tick, increment or decrement the "mouse pointer" counter for that axis depending on the state of the ?DIR bit. In my code, I use one of the POKEY timers to generate an interrupt at approximately 1600 Hz which seems to be fast enough to not miss transistions at "reasonable" trak-ball speeds.

When the switch on the Atari Trak-Ball is in the "joystick" position, the circuitry inside the Trak-Ball will "simulate" the switch closures of a joystick corresponding to the direction of ball motion.

Heh; you're lucky! I'm the same way and I'm only 25, and I've BEEN this way (too busy to do all the things I want to) since I was about 6 ! No kidding, I have lists and lists of "things to try out" that go WAY the hell back...

I plan to retain a segment of time for "experimenting/hacking," whether with my Atari or whatever else takes its place in my life, forever! Come Hell or high water, I am NOT going to give this up - it's my LIFE! Don't sell yourself short. I'm not going to have kids in the foreseeable future, nor get married, nor own a house unless it comes with maintenance and servants... ;-) They can call me a nut, "that guy who lives in the shack full of electrical stuff," if they want to, but hey, I love it...

> In fact, before I found a used Koala pad (I
> REALLY WANTED one BADLY!), I was considering building a gadget
> described in that column (issue #/month escapes me just now) that
> emulates the Koala Pad (but may need an extra button to do this with
> MicroIllustrator). The device was named the "Rodent" and used a R-
> Shack type joystick pot (a joystick "innards" with 2 variable
> resistors at right angles, for you "software only" types. :-)

Hey! I have one of these in a box of electrical gadgetry given to me by a friend -- see if you could dig up the issue # / month, willya? (Now all I need is to find someplace that archives the MAGAZINE... local facilities are pretty sad...) Or Xerox the article or info if YOU have it, send me Email to get my real address, and mail me the Xerox's... :-) This gadget sounds like a lot of fun... (Same goes for lightpen plans, if you have any!)

> I want to try to write my own flight
> simulator someday, just for gliders (sailplanes), and a relatively
> simple one (little if any recognizable scenery, no fancy instruments,
> etc.). The "Rodent" would be a great stick for such a "bird." Now,
> what to use for rudder pedals? ...

... which brings me to the crux of my topic! How about using two of those pedal-thingies like my Mom used to have to control her sewing machine? That seems to be a variable resistor (okay, Dad, RHEOSTAT, happy now?) in a pedal-type casing... It should be MODIFIABLE, at least, if not usable as-is... Of course, it would lack the "push one down and the other comes up" interlink-

age, but you could maybe build something....

>
> Remember, a mouse is just an upside-down trackball with a tiny ball,
> where the mouse pad (table) is your hand... (essentially). Input
> devices are fun to play with (even if only in your head).
>

Right you are. I picked up a 9-position thumbwheel switch somewhere long
ago, and hooked it up to provide direct single-digit input to the joystick
port. The thing's contacts were made-and-broken in 4-bit BINARY...
And you could build a "pantograph arm" with pots at the "shoulder" and "elbow"
to translate drawing motions to screen positions... (That wouldn't happen
to be what they did in the "Rodent", now did it?)

> So, I sincerely wish any and all "hobbyist hackers" the best of luck,
> fun, and so on with their Ataris. (And if this article is too
> verbose/long for anyone, please accept my humble apologies.

> option!)
>
Don't worry about it; you're not alone. I'm the same way. Note that I matched
you pretty well, bytecount for bytecount.

We verbose types have to stick together.

So tell me where Naperville is and maybe we can gab sometime...

Not having a catalog in front of me, I will refer you to the "source".
Hybrid Arts in the Los Angeles area is the only vendor to my knowledge that
has ever produced/sold MIDI hardware and software for atari 8-bit.
I have their MIDI box (connects to standard 8-bit daisy chain) and some
software (16 Track Sequencer for 130XE, DX7 librarian/patch editor).
They also had the same sequencer (with fewer features and memory) for the
48K machines. I believe there is more software (? librarian for Casio stuff?)
but am not sure. I suspect they are no longer making any NEW software for
the 8-bits. Although I have used the software only "lightly", it is quite
full featured (the sequencer, that is). If you have more specific questions
I can research same -- you will have to judge how it stacks up against
ST software (including theirs).

Oh yeah, they were also selling a software product similiar to the AMS(?)
program, but for MIDI not the internal voices. I.e., a 3-voice "word-
processor" for music, written by a group of folks in the SF Bay Area. I saw
a demo of it a year or so ago. You could program nested loops of musical
events, "subroutines", etc. Interesting. A programmers music machine rather
than a players.

> Is it true that it comes with NO R: handler?? That is almost,
> but not quite, unbelievable.
>
Yes it is the SX212 and yes, it comes without an R: handler. Atari is
going to package the terminal software (SX Express), the R: handler and
an SIO cable and sell it to 8bit owners. This keeps the cost down for
an ST owner that buys the modem and doesn't need the rest of the stuff.
Most of the BBS's around here have a program consisting of AMODEM with
an R: handler attached that seems to work fine for all that have tried it.
There is also some (prerelease?) version of SX Express floating around
that people seem to like also.

943. New Atari XF551 Drive Not Compatible With All Comercial Software

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-27 01:49:23 UTC
From: kevin@voder.UUCP
Message-ID: <3072@voder.UUCP>
Source record: 117147

I read something recently which points out a possibly serious problem
for some users of Atari's new XF551 disk drive. This is from an article
published in the March '88 newsletter of the Bay Area Atari Users Group
(BAAUG), I should point out that I do not own an XF551 and haven't been
able to confirm this problem but the article sounds correct.

When non-Atari users buy 5 1/4-inch floppy disks they have to purchase
either soft or hard sectored disks depending on their drive. If you look
at the disk you will see a small hole in the envelope next to the large
center hole on the side of the write-protect notch. This is the index hole.
If you now rotate the disk inside its envelope a small hole in the mag-
netic medium will appear. If the disk is soft sectored there will be one
hole, if hard sectored their will be several, usually 10 or 16 depending
on the number of hard sectors it uses. Soft sectored disks use this index
hole as the starting point for the software created sectors when formatting
a disk. Hard sectored disks use the holes to mark where each sector starts.
Atari users don't have to worry about this as neither the 810 or the 1050
drive have the LED sensor which reads this index hole(s) so they can use
any type of 5 1/4-inch floppy disk.

But the XF551 does read this index hole. If you flip the disk over, like
if you were going to write to the back side of the disk, the index hole is
now on the wrong side of the disk and the index sensor will be unable to
read it so you cannot write to the disk when it's in upside down.
So what? It's a double sided drive, you're already writing to both sides
of the disk so why turn it upside down? Well, what if you've got Print Shop?
Print Shop REQUIRES you to insert the disk upside down so it can read the
back side, but in an XF551 YOU CAN'T!. Plus, Atari 8-bit software is hard
enough to find as it is and when you do it's usually on the BACK side of a
Commodore disk! These disks will not work in an XF551!

Seems that this makes the XF551 a good second drive but not much good if
you've got a lot of 'flippy' software, unless you modify the drive so you can
switch the index sensor on/off manualy. If anyone has an XF551 I would
appreciate it if they could confirm or disprove this.

944. Re: C compilers, Re: 256K, Re: stuff

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-27 06:42:53 UTC
From: conklin@eecae.UUCP
Message-ID: <6200@eecae.UUCP>
Source record: 117148

Hi group. Trying to cut down on News, so this sez assorted things.

On C compilers, DONT post Ace-C. It's not the best. However, I'm not sure you'd want to rush off and claim CC8 as best either.

There is a generation of C compiler for the 8 bit BEYOND Ace-C. In fact, it is drastically superior to Ace-C. It is called DVC/65 (Development Compiler for the 6502, not Deep Violet) and was written by Ralph Walden.

You may know this product today, as, after making it a "shareware" type product that was free for all and $35 for the docs and a couple more files, (a great deal,) the author decided to remarket it and you now see it in magazines as "Lightning C" I am not aware of any upgrade to the product but they are likely to be some.

Mr. Walden pissed me off though when, after mentioning this program to the net, he told a netter that called him that some "pirates" had gotten ahold of his software and it was never released. This was an outright, stinking blatant lie. In fact, both myself and a couple friends had independently been conversing by letter to Mr. Walden in which, many times, he of course refers to the shareware nature of his product. I don't know what he thought he would get away with by lying to someone, but I _kept_ all those letters and will gladly show written proof, FROM THE AUTHOR, that DVC/65 is in fact shareware.

Meanwhile, if you are interested in a slick C compiler for the 8 bit that even includes an optimization pass, I will see what I can do about posting the shareware package that was originally released.

.....

For 256K Mods. The original 256K upgrade was designed by Claus Bucholz, and written up in the 10th anniversary Byte magazine. Atari released the 130XE _after_ that upgrade, so he did a quick change and made his mod XE compatible. Several manufacturers later came out with upgrade boards that followed this mod.

Unlike John, however, I do not reccommend the Newell. In fact, I reccommend anything BUT the Newell 256K board. From what I have seen running my own extended memory software, the Newell people somehow did something slightly different from all other upgrade boards. Unfortunately, I didn't have the opportunity to find out what.

All known software and documentation related to extended memory Ataris is religiously hunted and kept on the Club II BBS in Detroit. I have recently made a second copy of ALL the information related to upgrades in a single ARC file. This file is rather large though and cannot be

downloaded and de-arced on a single density drive. All the information needed to build your own upgrade is included, complete with the information on how to build not only 256K XLs, but 320K XEs, 576K XEs, and even 1 MEG XEs! (No one said it was rational.)

The MTOS multitasking kernel requires Claus compatible 256(or more) of memory. Another (massive) package is THE WORKS, a Page-setter style typesetting program that uses all 256K of memory. Available on the II as well.

I would reccommend getting all the info on the upgrade and examples of the software at minimum before you purchase an upgrade board. I do, however, heartily reccommend and upgrade BOARD as opposed to a direct wired mod.

Blast, can't remember the third thing. Keep on hacking those 8 bits!

Whoever has a set of FAST, WORKING joystick port serial routines, yes, please look them up and post. Many people have tried. High speed, however, is a new claim. If you have routines like that, we want em!

945. Reply to Hennie Kretschmann about prob. with joystick ports...

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-27 12:33:06 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8802271233.AA24125@mitre-bedford.ARPA>
Source record: 117149

My reply direct to Hennie Kretschmann was returned by an irate mailer, so I've re-posted it this way. Perhaps it will be of general interest anyway.

Hennie asked me if I could explain why he sees "timing jitter" when trying to generate periodic pulses on the joystick port outputs.

I think that what you are seeing may possibly be the "Vertical Blanking Interval" interrupt which occurs whenever the monitor reaches the bottom of the screen and returns to the top. During this time, the CPU is interrupted and has to do some housekeeping chores. In Europe I think this interval is 1/50 second. In the U.S. and Canada it is at 1/60 second since the power line frequency here is 60Hz.

For a pulse generator, you might look at programming the POKEY chip to generate the pulses. I think that will give a perfectly periodic output.

For an RS-232 device, you could use the serial peripheral port, which requires only some level converters, e.g. MC1488 and MC1489 to convert to RS-232 levels, and a new R: driver that knows how to use this port. There was a commercial device called the R:Verter which did this, and the driver program is floating around if you can find someone who has it. This output is also generated by the POKEY chip so should be free of the timing uncertainty due to the VBI processing.

You could probably also use the joystick ports, but you might have to turn off the VBI interrupt (causing the screen to go blank) if the timing "jitter" is too much.

I hope these comments are helpful. You might find "de re Atari" fun to read if you can get a copy of it.

948. SX212 fun 'n games

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-29 01:47:55 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <2229@bsu-cs.UUCP>
Source record: 117152
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

In response to the recent fever of SX212 praise and wonderment, I gave in and went out and bought one yesterday, intending to UNPLUG my existing modem (which talked to my Atari through an 850 Interface and so-called "standard" RS232C cable) and plug in the SX212 instead. I had it on good authority (this net) that you could indeed do this, with no hassles.

I got the modem for about $99 (came to $103.95 with the 5% sales tax here in Indiana), brought it home, unplugged the old modem, plugged in the SX212, and threw the switch. Nothing happened. It didn't work. The SX212 would indeed talk to my Atari - accept Hayes-like commands, respond with "OK", and all that. It did NOT, however, even so much as ATTEMPT to talk to the PHONE LINE! It just sat there and did NOTHING. I was devastated.

Before collapsing in cardiac arrest, however, I checked the documentation, and was astounded to find that this very problem was in fact covered in the section on "Troubleshooting." The problem, it turned out, was that the "DTR" (Data Terminal Ready) line of the RS232C connection was NOT PRESENT. Oh. I tried a few more 850 Express! commands, but nothing made any difference vis-a-vis bringing up the DTR signal. Finally, checking the cable itself, I found that not only was there no signal on the DTR pin of the cable, there wasn't even a PIN at the proper location (pin 20 of the 25-pin) in the connectors! My old modems apparently didn't mind, but the SX212 can't deal with it. So for the past day and a half I've been searching for ways to fix MY cable, replacing pin(s), connector(s), and/or whatever else I could find. Radio Shack (forgive me; I was desperate) had an RS232C cable and a "serial port adaptor" for ITS line of equipment, which had the correct number of pins on both ends, but after bringing it home I found that the particular pinouts were wrong.

Finally, good ol' Dave P. (aegnor@bsu-cs) stopped in, and suggested that perhaps the oft-mentioned "Club II BBS" would have an alternate R: handler that would let me say goodbye to the RS232C and 850 arrangement, and simply connect the SX212 directly to the SIO port. We quickly logged onto the Net, got the Club II BBS phone number, dialed into it, found "RVERT212" in the File Section, downloaded it -- and, to make a long story just a little shorter, HERE I AM, TALKING TO YOU VIA SX212, "RVERT212" R: handler, and the KERMIT65 (minus contained R: handler) that was posted here a few months back!

It WORKS, gang! Go out and get 'em NOW!

This thing is BEAUTIFUL, in operation AND in appearance. Even my non-computerholic girlfriend calls it "the squirt" because "it's so cute!"

Anyway, that's my tale, which had an unexpectedly happy ending. I'd like to thank John Dunning for porting Kermit65 in the first place, and whomever it was (I forget, sorry) who posted the Club II BBS info here! The entire face

of my telecomputing experience has been changed beyond recognition, much for the better, due to you guys. Have a happy!

950. Re: My Percom Disk Drive Troubles [Info-Atari8 Digest V87 #114, etc.]

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-29 13:58:16 UTC
From: Fleysher.WBST@XEROX.COM
Message-ID: <880229-055822-1119@Xerox>
Source record: 117154

I was unable to reach Rich!Jolnet, but thanks to him and others for their suggestions. Here's a recap for you Percom Floppy Drive owners out there.

Late last year my Percom SSDD drive developed an intermittent thermal problem - after warming up a few minutes it would neither respond to the Atari nor initialize successfully. (No D-D-D-D-D-whirrr, just a feeble d-d-d-d-d.)

Most of the suggestions I received were to replace and/or solder in the three power regulators on the back panel because of the lousy sockets.

I finally got some time to poke around with my voltmeter and a scope. Two regulators had solid 5V outputs and the third had a solid 12V output. So I looked around for open input logic levels and reseated the socketed IC's on the Percom controller board. All of a sudden the drive started working again! (Some strange waveforms I had spotted still look the same - they have slow S-shaped rising edge transitions.)

Moral of the story: reseat everything that is socketed before you give up and send the drive (or any other piece of equipment) off for maintenance.

Thanks for the suggestions, those who responded. Case closed - for the present at least....

Dan

I have written a simple musical keyboard for the Atari 8-bit computers.
The only trouble is that the notes are not accurate (some of them seem
a bit flat) and that I only have a true 3-octave range. I get a 4th
octave through the use of distortion but it does not sound very good.
I am aware that by combining two of the voices I can get 16-bit accuracy
and greater range. I am capable of doing this, however, I do not know
what numeric values are required to produce each specific note
(eg. 'middle C'). If someone out there has a table with this info
could you please send it to me either through e-mail or through
the bit-net. Please don't just refer me to DeRe Atari as I do
not have access to that publication.

If I can get this information I will be able to greatly improve the
quality of my musical program. When this is done I will be
willing to either post the program to the bit-net or send it
to people through e-mail.

I sent a similar request a long time ago but lost my computer access
(ie. the semester ended) before I was able to see if there was a
reply.

Thanks in advance for any help.

The composite output from the 65XE, as with most all 8-bit Atari's, is compatible with any video monitor or TV configured for composite signal input. A direct connection from the computer to the monitor is proper. A better resolution in the picture quality is achieved by the elimination of the RF transmitter/RF receiver portion of the computer/TV combination. Some degredation of signal quality by the RF path.

The alternate monichrome configuration to composite is where vertical and horizontal sync, and video are brought out separately for use by the monitor. Composite video is the preferred output as it is easier to handle.

As for 80 columns, most color TV screens do not have enough pixel resolution to support 80 columns adequately. That is why most 80 column systems tend use a monichrome screen. Many patterns of character generation have been tried for color TV screens in an attempt to achieve high resolu
80 columns is a tough road for a color TV monitor.

Lightspeed C (not Lightning C) is not the last word in C compilers - in fact, it is Ralph Walden's rewrite of the ACE C compiler. It's functionality is limited, and the compiler is not as complete as the CC8 compiler. I think it has a nicer user interface, though. I don't know this for sure, however, since I never bought the Lightspeed C compiler - I was considering it, but as soon as I found out that it was less complete than CC8, I decided not to.

I am not sure about the 65XE (since I don't own one), but I felt the need to point out that the 130 XE has a color alternative to the composite output. There are 2 other pins in the 5-pin DIN connector (which ones I can't say now, as my manual is at home - but look in a 130XE manual if you can borrow one) that provide 2 signals: one, the "chroma" [chrominance], and the other, the "luma" [luminance] signal. There are also some monitors, that cost about the same as "ordinary" color monitors did a couple of years or so ago, that accept these signals. The one I have is a Commodore 1802C. I bought it at a local discount store (Service Merchandise). All I had to hack on was the cable that came with the monitor: replace the Commodore 8-pin plug with a 5-pin plug, using the 130XE and 1802C manuals as a guide.

It works quite well, and provides enough resolution for use with 80 columns, at least for the 80col. display provided by OMNIVIEW, which is a very well-worked-out GR. 8 - based rendition of a character set. I am sure that a monochrome monitor would appear even sharper, but I didn't want to play "musical monitors," and where would I put it? (I looked for a composite monitor with a mono. mode, but never found such a beastie. Existence proof, anyone?) Oh, yes - all the other graphics is sharper with the chroma/luma monitor too, although artifacting is mostly [entirely? Super 3D Plotter II seems to be able to use it still] gone. If anything, it's the artifacting that makes the composite 80-column display unreadable (all I have to do to see this is change cables and switch the 1802C to composite video mode).

I have a 320K XE (Peterson upgrade) and it works great. I really love the thing, but I have a few problems running some software written on it. It appears that some of this "extended memory" software, such as the PD type-setter, "The Works", will work on a 256K 800XL, but not with the 320K 130XE. Does anyone know why? Does anyone have a software emulator that will circumvent the problem? I want to run certain software, but I just can't because of this. Any help will be greatly appreciated.

Source record: 117062

I am using OmniCom with the P:R: connection for the first time and have a problem with the printer. It hangs !!

When I try a print screen using SELECT+OPTION, or capture to printer, I hear the program trying to access the printer, but it never succeeds. It just trys foreever.

Does anyone have any experience that might help?

I did have some problems previously accessing the printer through the P:R: connection from XLEnt Word Processor, but it appeares to be working OK now.

Thanks for your help.

The full documentation on OmniCom is still, as far as I know, available from David Young, 421 Hanbee, Richardson TX 75080. When you send in your $10 Shareware fee to David, he will send you a disk containing the latest version of OmniCom, minus the Shareware message on the front and containing the user manual in the file OC.DOC (or some such name). As I understand it, support for David's other products (and probably also OmniCom) are now available through Wes Newell of Newell Industries, 602 E. Highway 78, Wylie, TX 75098. Newell's phone number is (214) 442-6612.

The OmniCom manual is very clear and complete and well written, and explains a lot of details in addition to the question you asked. It is certainly worth the $10 fee, if you plan to use OmniCom seriously. (If you have a conscience, you also gain the good feeling of being a legal user, too.)

However, in case you want to play around with the keypad to help you decide if you want to pay to become a long-term legal owner, you'll find that the keypad keys are over at the left end of the keyboard. Specifically, the leftmost four columns, plus B and N.

For what it's worth, I have found OmniCom to be an extremely satisfactory substitute for a real vt100 in talking to my VAX at work from my Atari at home. The keypad feature makes it highly useable for my application.
It acts so much like my vt100 at work that I have no trouble at all swapping back and forth between the two terminals. If you need to do screen editing, with keypad commands, it's still the only game in town so far as I know. Not only that, but it supports XMODEM and ASCII capture as well as KERMIT, and as the "icing on the cake", it has a built-in "PRINT SCREEN" function that I find immensely useful for quickly capturing short e-mail messages on paper. At $10, I think it is one of the best software values around.

-John Sangster

(I have no financial interest in CDY Consulting or OmniCom.)

961. 320KXE Peterson Upgrade...

I am not familiar with the 320K Peterson upgrade, but am fairly familiar with the Newell 256KXL board. I know that it is tricky to get even 256K to be addressable while maintaining compatibility with the 130XE extended memory mapping scheme. If you have a description of the Peterson upgrade's addressing scheme, I might be able to help you figure out what is going on. They may be using a different address to control the bank switching, or they may be using the same address ($D301) but using the bits differently.

By the way, I'd love to get a copy of "The Works" if, as you said, it is Public Domain!

I have an 800XL and a 400, but only one disk drive (a 1050).

I've rigged up a connection whereby both the 400 and the 800XL can be
connected to the disk drive through the Atari serial IO port - of course,
both machines cannot do serial IO simultaneously but:

- can both machines be chained to the drive, and both be on (although only
one is doing IO at a time)?
- if NO to the above, can both machines be chained to the drive, with only
one machine on at a time?
- if either of the above occur, can anything be damaged?

Thanks in advance,

John

965. Trak-balls

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-04 16:09:33 UTC
From: lackey@Alliant.COM
Message-ID: <1341@alliant.Alliant.COM>
Source record: 117069

Yes! I did it! All by myself (almost)!

I have a program for interfacing the trak-ball to Basic (or anything else). An assembly routine, which safely resides in page 6 and uses the pokey timer interrupt, tracks the trak-ball and places its position in two bytes in page 0, where it can be read by PEEK's.

The regular interrupt, plus the handler, run continuously, and only seem to slow down main execution time by 5% or so. I like the trak-ball, not only to replace the joystick, but even more so, to replace the paddles (only sideways motion is used).

Would be happy to share. -Stan

966. Wanted, PD atari 8 bit software

967. Indus and Z80

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-05 03:19:16 UTC
From: swklassen@trillium.waterloo.edu
Message-ID: <5536@watdragon.waterloo.edu>
Source record: 117071

I have an Indus GT disk drive and desire to be able to program the Z80 processor which it uses. One possibility would be to purchase the package offered by Indus which would increase the RAM available to the Z80 and use the Atari 800XL as a 'dumb' terminal for the Z80. However, I do not want to spend the money for what should be a cheap upgrade. There are four things which I am looking for:

1) the schematics of the drive
2) pinouts for the serial ports
3) what (if anything) can the 'aux' dip switch be used for
4) a memory map of the Z80 in the Indus (I need to know where to put the new RAM).

If anyone knows where I can get this information (ie. can I get it from Indus, I heard that they sold out to another company or something?) please let me know through e-mail or post it to the BITNET if others are also interested.

Thanx

Greetings all. I have noticed that there is a good bit of talk about posting good PD programs and not much actual posting. For example, I have been looking for Kermit-65 and a good C (Lightspeed, it seems, may be the best). If you think a file could have widespread use and/or it has been requested, it would be reasonable to make it available. I am relatively new to the net, but I have found a couple ways to handle file distribution. I see one of the better ones being uuencoding and posting to the net. The next option is also a question: are there systems that specialize in distributing Atari software (via ftp, etc.)? That might work. I have also heard of LISTSERV, but I could use more info if you would like to help.
For my contribution, I offer Daisy Dot II and Codebuster. DDot II is a rewrite of the original with lots of enhancements. It is in C now so it will work with SpartaDOS. It now is a full text processor with underlining, boldface, switching fonts, centering, shift left/right, and the list goes on. Utilities include one to change Atari character set files to .NLQ files. Codebuster is a great little utility for the ML hacker. It does many things, not the least of which is the conversion of binary load files into Atari Macro Assembler source code. Great for the hacker with a lot of patience. If anyone would like either one, let me know & I will get it to you. They can both be legally distributed (I don't use PD because the term has become so narrow).

> for Kermit-65.
This is a repost of the kermit.65, it will have the original poster's
notes and is in three packages. I do hope somebody will tell Gary and
I how to get programs out of LISTSERV, I have been able to get all kinds
of information, but no programs.
I will send the kermit in three files separate from this one.

Stephen Grove, Pac Bell Rohnert Park, Calif.

972. kermit.65 repost

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-08 20:55:07 UTC
From: seg@pbhya.UUCP
Message-ID: <10853@pbhya.UUCP>
Source record: 117076

Lines: 976

This is a repost of Kermit-65, with bug-fixes and enhancements in
response to the feedback from the first release. The three parts are
the revised documentation, following this text, and binaries for
KERMIT.COM and KERMITNR.COM, exactly the way the first posting was done.
Please see the documentation for a description of the changes since
first release. (Yes, the infamous binary bug is fixed).

Archive maintainers: Please replace any old versions of Kermit-65 with
this one.

Here's the doc:
--------------------------------kermit.doc--------------------------------
Kermit-65 Manual and bug list Page 1

Kermit-65 for Atari 800s

By John Dunning. Bug reports to me (JRD@Symbolics.COM) via Arpanet.
Other net users will have to find some way of getting mail to Ar-
panet, then use the above address.

Kermit-65 is a port of the kermit-65 available for Commodore frobs.
It runs on 48K Atari 800 family machines. Current version (second
release) is 3.3.

Capabilities:

File transfer, text and binary:

Without going into excruciating detail here, Kermit-65 is a fairly
complete implementation of a user side, using the KERMIT protocol.
It's been tested against Kermit-11 under RSX, and C-Kermit under
VMS and Un*x, and seems to work fine. For a description of what
the KERMIT file protocol is all about, and something about how the
it works, see the 'Kermit protocol' section at the end of this do-
cument.

Terminal emulation:

Glass tty, Vt52, or Vt100. Supports 3 flavors of screen
configuration; Atari standard screen, 80-column pannable
(40-column visible) like VTERM, and 80-column graphics, like
V10SQR. Terminal emulation modes may be used in any combination
with screen configurations, though some combinations won't work
real well; for instance trying to do full-screen Vt100-style ed-
itting when using the Atari screen is a good way to lose.

Local file management:

Kermit-65 includes Directory, Erase, and Rename commands, allowing the user to do most kinds of maintainance operations without leaving the program. It also allows you set set the default drive to any value 1 thru 8, so you're not stuck using a single drive for everything.

Typing at Kermit-65:

The command processor accepts command lines, consisting of a keyword, optionally some more keywords, and optional values. Things in command lines are delimited by spaces, and terminated by <CR>. At any time, you may type '?' to get a list of valid completions for the word you're typing. You need not type keywords completely; however much uniquely identifies the word you want is enough. At any time, <ESC> will attempt to complete what you've

typed so far. Note that if you've typed a word, but haven't hit a <space> or <ESC> yet, so that the cursor's at the end of the word, '?' will tell you that there's only the one possibility. Hit a space, then '?', for a list of possibilities for the next word. Some commands are 'defaults' in the sense that if you type something non-unique, and hit escape, and one of the possibilities is a 'default', it will win over the other possibilities. One example of this is 'Send'.
Example: The following illustrates a typical interaction between you, the user, and Kermit-65. The stuff that Kermit types (prompts, echos of partial commands, and help) is on the left, stuff typed by the user is in the middle, and commentary is on the right.

Kermit types: You type: Comments:

"Kermit-65>" Kermit prompts.

"s?" User starts typing a
command starting with
"s", then hits "?" for
help.

"Keyword, one of the following: Kermit prints possible
set show for "s"...
send
Kermit-65>s" and reprompts, with the
partial command.

"et?" User finishes the "set"
command, and asks for
help again.

"Keyword, one of the following: Kermit prints the (one)
set possible completion.

Kermit-65>set"

" ?" User hits a space, then
asks for help again.

"Keyword, one of the following:" Kermit prints possible
(various subcommands of 'set' here) completions for words
that can follow "set"

Kermit-65 Manual and bug list Page 3

Kermit-65 commands:

Bye
Tells the kermit on the other side to log out, and ex-
its Kermit-65.

Finish
Tells the kermit on the other side to exit server
mode, but stay logged in.

Connect
Puts Kermit-65 in terminal mode, using whatever param-
eters are currently set for Terminal and Screen confi-
guration. See 'Set Terminal' and 'Set screen' for
more details.

Quit
Exit from Kermit-65 back to Atari DOS.

Exit
Same as Quit.

Get
<file spec>
Ask the kermit on the other side to send the named
file, using whatever file and protocol parameters are
currently in effect. See 'Set' for more details.
Note that <file spec> may be wildcarded; assuming the
serving kermit allows that. In that case the serving
kermit may send several files; Kermit-65 will try to
receive all of them.

Send
<file spec>
Send the named file to the kermit on the other side.
If the file spec is wildcarded (using DOS FMS wildcard
rules) all matching files are sent. In the latter
case, the Kermit on the other side should be in Server
mode, so that it can deal with a whole sequence of in-
coming files.

Receive
<file name>

Attempt to receive into the named file. Assumes the other kermit is already trying to send it. If no file name is given, Kermit-65 will attempt to get the name from the file-header information coming from the other side. This is the command to use after telling the other kermit "Send <something>".

Kermit-65 Manual and bug list Page 4

Set
Baud
(50..9600)
Sets baud rate on the comm port to the supplied value.

Parity
Even, Odd, Mark, Space, None
Sets specified parity for the comm port. See the Atari 850 man for more details on the behaviour of the various parity options.

Word-size
Seven, Eight
Set frame size used for comm port. The default is eight-bit. The preferred value for this depends on what the parameters of the serial line are set to on the other side. In my experience, older systems will tend to use seven-bit configurations, more modern ones will tend to use eight-bits. If you're not sure, it usually works to use eight-bit.

Default-disk
<1..8>
Sets the default disk for all file operations. Legal values are 1 to 8, inclusive.

Rs232-registers
<16-bit hex number>
Directly sets some of the the values used when configuring the serial port. Specifically, the high byte is used as the AUX1 parameter for the XIO 38 (configure translation and parity) and the low byte is used as the AUX1 parameter for the XIO 36 (configure baud rate and word size). This allows settings to be used that aren't covered by the supplied keywords in Baud, Parity, and Word-size.

Debugging
Off, Terse, Verbose
Turns on/off various debug msgs strewn around in the code.

Eight-bit-quoting
On, Off

Turns on/off eight-bit mode quoting in the kermit protocol. The default is off.

File-warning
On, Off
When this mode is on, Kermit-65 will refuse to overwrite files when receiving. When it attempts to receive a file that's already present, it will alter the filename of the incoming file so as not to overwrite the old version. The algorithm for altering the filename is to replace the extension field of the name with a 2 digit hex number, and retry. If the file still exists, the number is incremented. This repeats until a free name is found, or the extension reaches "FF", at which time the receive is aborted. (I think it's never possible to get that far anyway, as you can't put 256 files on one of these disks)

File-type
Atascii
This is a standard atari text file, and is the default mode. End of line is signalled by the ATEOL character ($9B). When sending, other ATASCII characters are translated to their ASCII equivalents, ie ATTAB ($7F) -> Tab ($09), ATRUB ($7E) -> Rubout ($7F). The file header info generated indicates that a text file is being sent. Receiving one does the opposite transformation.

Ascii
Files are sent/received as ordinary ascii-text. Line terminators are assumed to be CR ($0D) followed by LF ($0A), and are handled in the usual kermit fashion. No translation of data happens. This mode isn't the right thing for regular old text files, but is useful for sending around files that are output in plain ascii from various utilities. For example, I have a word processor program which produces formatted output files in ascii, intended to be dumped directly to a printer. This mode gets them over to my pdp-11's print spooler.

Binary
Data is sent in kermit binary form, no line terminators etc.

Flow-control
On, Off
Turns ^S^Q flow control on/off for the incoming line. See 'Com port handling', below, for more details.

Ibm-mode
On, Off
Turns on/off 'IBM mode'. This is apparently a standard thing in kermit implementations, made necessary by the wierditudes designed into the blue equipment. This code has been left as is, so it's got some chance of working, but has not been tested.

Local-echo
On, Off
Controls echo mode in terminal emulator. Default is off.

Send
End-of-line, Padding, Timeout, Pad-char, Quote-char, Eight-bit-quote, Packet-length
Sets one of the listed parameters for the transmitting side of the kermit protocol. Padding, timeout (seconds), and packet-length are in decimal, the others (character codes) are in hex. This command is primarily used when talking to a kermit that can't or won't use the standard set of protocol characters for beginning-of-frame, end-of-frame, etc. As such, it's not generally useful, at least I've never seen a kermit that required it. There are things that might come in handy, though. For instance, if you've got an exceptionally dirty phone connection, you might want to set the frame size down from the default of 94. In that case, you might say "Set Send Frame-size 30". Note that Send parameters can be reset by the other Kermit sending one of the kinds of packets that request certain values, so you may have to tell him directly, to get the effect you want.

Receive
All parameters settable same as 'Send'

Screen-driver
Atari
The standard 24x40 Atari screen driver. This mode does its output to the internal E: device. This isn't very useful for complicated things, but is supplied in case kermit's running someplace where there's not enough memory to do anything better. (Besides, I had to have all the code for it lying aound for other reasons, so why not?)

40-column
A 24x80 screen, using the character CTIA mode. Since

that mode only allows 40 visible columns, the screen
is pannable left to right, allowing any 40-column
chunk to be displayed. The terminal code will attempt
to keep the cursor visible by panning around while
output is happening. You can also pan manually using
the Start and Select keys. In this mode, reverse- vi-
deo output works, but none of the other highlighting
types.

80-column
A 24x80 screen, using the hi-res (320 bits/raster)
graphics CTIA mode. In this mode, both reverse video
and underlining are supported. This is the default
setting for screen mode.

Terminal-emulation
Vt100, Vt52, None
Sets the terminal emulation mode to the specified va-
lue. The default is Vt100.

Show
any of the same keywords as 'Set', or 'All'
Display the value(s) of the specified thing(s). 'All'
displays the values of everything in sight.

Status
Dump various goodies about the last file transfer; characters
in, out, naks, timeouts etc.

Directory [<filespec>]
Display a directory list from the default drive. <filespec>
is optional, if omitted, it defaults to "*.*".

Rename <from-filespec> <to-filespec>
Does a rename operation on files on the default drive. Either
filespec may be wildcarded, in which case the rename operation
happens according to the rules described in the ATARI OS FMS
documentation.

Erase <filespec>
Erases files on the default drive. Filespec may be wild-
carded, in which case the erase operation happens according to
the rules described in the ATARI OS FMS documentation.

Save
Dump Kermit-65 parameters such as screen settings, send/re-
ceive parameters, etc to an init file "KERMIT.INI" on the
default disk.

Restore
Read parameters from "KERMIT.INI" back into the running

Kermit-65.

Help
Gives a summary of the above command list.

Other interesting things about terminal modes:

Depending on what terminal you're using, there are several things which may be of interest. In 40 or 80 column modes, there's a status line under the 24 data lines. It displays what special keys are active, and the status of the comm port. In 40 column mode, Start pans the screen right, and Select pans left. In both 40 and 80 col modes, Option is used to get the kermit's attention. In Atari mode, c-Y is used instead.
Once you have kermit's attention, it wants a character; one of:

C Break the connection
B Send a break (approx 1/4 sec)
S Display status

Function keys:

Kermit-65 can generate function key sequences ala VT100. The current function key bindings are as follows: (c-sh- means control-shift...)
c-sh-0..c-sh-9 keypad 0 thru 9
c-sh-. keypad dot
c-sh-backspace keypad minus
c-sh-, keypad comma
c-sh-return Enter
c-sh-q..c-sh-r PF1..PF4
c-sh-- Up arrow
c-sh-= Down arrow
c-sh-< Left arrow
c-sh-> Right arrow

Other key bindings for things not on the Atari keyboard:
sh-< { (left brace)
sh-> } (right brace)
sh-backspace ~ (tilde)
c-sh-backspace, or c-7 ` (backquote)

Kermit-65 Manual and bug list Page 9

These key bindings aren't quite what I had in mind, but the OS rom won't let me get at all the control-shift keypresses, so they'll have to do for now. I encourage any feedback about how these feel. I've been using them for a while now, and they don't seem as bad as I expected. In particular, they work passably well when using EDT (I'm typing this document with it), which I think is an indication that they're useable, as it's a real keypad hog.

Other special keys:

The Atari key (/|\ on 800 vintage dinosaurs like mine, |/| on newer 800XL vintage equipment) behaves in a special fashion when using Kermit-65. It toggles a flag that causes input from the comm port to be held up, rather than processed as soon as possible. This is useful for causing the screen to hold up temporarily when in terminal mode. If flow control is enabled, it behaves in the expected fashion; it'll tell the other side to shut up until you press the Atari key again, to let pending input be processed again.

The status line:

When in 40-column or 80-column terminal modes, there's a 25th line below the usual 24 lines of terminal screen. This is the status line. It will look something like this:

K65: Option + o v Rs ok

There are several interesting things displayed here: At the left side, after "K65", is a list of which special keys (option, select, start) are active at the moment. If you press Option, this will change to a prompt for the special characters that can follow Option. In column 22 ('+', above) will appear '+' or '-', or space. This indicator shows you the state of the flow-control logic; + means incoming traffic is enabled, - means it's disabled. Note that it when flow-control is turned on (see commands, above) this flag will toggle back and forth between + and - as the flow-control logic does its thing. If flow-control is turned off, it will just sit on + all the time. Column 24 ('o' above) will contain a blot if comm-port reading is suspended, space otherwise. In column 26, ('v') above, is the caps lock indicator. It will display an up-arrow if caps are locked, or a down-arrow if not. In column 32 is a message describing the last known state of the comm port.

Com port handling:

In its current configuration, Kermit-65 expects to talk thru an Atari 850. In principal, that ought not to be a restriction, but I (JRD) only have an 850 to test with, and don't know what requirements there are for other devices. I've tried to be scrupulous about sticking to the documented interfaces to things, however, so I'd expect any driver that adheres to the spec to work.

The port's opened and closed a lot; you'll hear it, as I've left the 'noisy bus' option turned on. It uses page 6 ($600) as an IO buffer. Since that's only 256 bytes, there's the possibility of overruns at high baud rates. When flow-control's on, Kermit will attempt to shut off the other side when it sees more than 50 bytes pending; it will turn it back on when there's less than 10.

As of this writing, Kermit-65 has been out in the field for a while, and seems to work ok with things other than 850s. One word of caution; I've gotten some feedback to the effect that the default timeout values I chose are too short for reliable operation at low baud rates. I've decided not to change the defaults, as you can easily change them in your KERMIT.INI file, and because most folks seem to have access to 1200 bps modems and things these days. However, if you're running at 300 bps and seeing reliability problems, try pushing the timeouts up to say 15 sec or so.

Other ramblings:

Version 3.3 loads at $2D20, and uses up thru about $B000. That means it'll only run on 48K machines. It appears to run fine on XL and XE equipment, but most of my testing has been on an 800, so there may be some problems. BTW, that load address was chosen because the latest version of DOS XL for Indus GT's uses up thru $2D14 when it's configured for two drives, and the 850 driver is loaded. Older versions of DOS XL take up less memory, as does DOS. I don't know what the requirements are for things like Spartados. If anyone comes up with a conflict, let me know, and I'll assemble you a version that's org'ed somewhere else.

On XLs and XEs, kermit-65 will require that the machine be booted with BASIC disabled, as it's not yet bright enough to detect that that's where it is and map out the cart. (if anyone knows how to do that, and feels like saving me some work...) Kermit-65 is available in 'bare' form, or with an autoloader for the 850 driver prepended to it. The bare version requires that you load whatever rs232 driver you're going to use first, then run kermit. The autoloader equipped version does that for you.

Kermit-65 Manual and bug list Page 11

For those of you who have YAU (posted separately) the byte count and checksum values for KERMIT.COM and KERMITNR.COM respectively are 24622, #x5F17; and 24408, #x1560.

Kermit-65 Manual and bug list Page 12

Credits

I blew it when distributing the first version of this document, and forgot to include this section. Mea culpa.

Many thanks to my beta testers, in particular Marshall Abrams, for his patience in dealing with initial versions of this thing, and for aid in making this document clearer. Thanks also to John Sangster for helping nail down my obscure terminal emulator bugs, and miscellaneous kibutzing. (Sorry John, I still haven't gotten in the key defining util. Maybe next version).

Kermit-65 Manual and bug list Page 13

Bugs and misfeatures:

There's no way to set the comm port to other than R1:. Does anyone care?

The help processor doesn't deal properly with upper-case, and thinks there are no completions.

Vt100 mode is missing still missing insert/delete character.

Blinking fields, bright fields, double-high, double-wide, and 132-col mode are not supported. (Reverse vid and underline are)

There's currently no way to set the screen colors.

It's possible to confuse yourself by hitting c-1 in terminal mode, as my screen drivers ignore it, but Atari's doesn't. You're fine until you break the connection, then everything appears to wedge up.

Flow control for the incoming side of the connection isn't implemented. This can cause problems when trying to send at high baud rates to a host that's got a stupid serial driver, or a small typeahead buffer.

The part of the command parser that deals with pathnames is completely bankrupt (that's what I get for using old code), and doesn't work properly unless it's told that a null pathname is legal. The result of all this is that when entering pathnames and asking for help before entering any data, it will tell you "input file spec or confirm with <cr>". Pay no attention to the man behind the curtain; you really do have to put a pathname in there for anything to happen.

Kermit-65 Manual and bug list Page 14

Bugs fixed for v 3.1

Save and Restore now actually do something, instead of being effectively no-ops.

Rename and Erase commands are now implemented. This means that virtually all file operations one cares about (while up/downloading) can be done without leaving Kermit.

File-warning mode has been fixed so that it really does something useful, instead of just bitching about the file conflict.

The pathname parsing substrate has been installed, so that defaulting and merging can be done in a reasonable fashion, instead of by ad hoc kludgery.

The screen hacking code has been cleaned up a good bit, so as not to be continually clearing the screen when doing transfers.

Logging code has been added to tell the user what files are being sent and received.

Status and help commands in terminal mode are now working.

The directory command now takes an optional filespec parameter.

Bugs fixed for v 3.2

Binary mode now works again. (Sheesh!)

Rename and Erase routines now make sure the comm port's closed before attempting to hack the disk.

The user interface has been cleaned up some; all numeric values other than character codes and some debugging info is now displayed and entered in decimal, rather than hex.

Bugs fixed for v 3.3

Fixed a dumb bug in terminal code that caused graphics mode to be entered at unexpected times.

Fixed file reading code so as not to get confused and generate an extra byte when running under non-standard things like SpartaDos.

Cleaned up Directory code; using new pathname-mapping substrate.

Added support for wildcarded pathnames in Send code.

Fixed packet-dumping debug code to not mask off top bit of char, and quote everything to keep from interpreting screen hacking chars.

Fixed init code to look for an init file on D1, and read it if found.

Fixed flow control code so as not to wedge up unexpectedly.

Re-enabled the suspend-input capability, using the Atari (/|\) key.

Break (Option-B) in terminal mode has been fixed.

Cleaned up the font used in 80-col mode.

Removed Speedscript file type, as Speedscript apparently just uses plain vanilla text files. Changed default file type to Atascii.

Added caps lock functionality, similar to standard Atari kbd driver.

Fixed a bug in terminal mode that was trashing the stack.

The Kermit Protocol

The following a brief description of the Kermit file protocol, excerpted from one of the many documents kicking around. If you already know what it is, or don't care, skip this section.

The Kermit protocol allows many (if not most) types of computer systems to effect, at minimum, error free file transfer with other systems and microcomputers over asynchronous lines.

Introduction

With the widespread use of personal computers the need for file exchange between systems has become of foremost concern among users and managers alike. There are many commercial products available which meet this need, some of which may offer more advanced functions such as transparent record oriented file access. Networks that do this, such as DECnet, can be expensive, and if your computer or microcomputer is not on the network your needs won't be met. Transfer of files with removable disks can work, but generally only when the computers are of the same type, it's not very useful when the systems are removed in location. Rarely will a larger mini or supermini be able to read a microcomputer's disk.

A more realistic approach, from both cost and convenience, is to find a way to use ordinary telecommunications and/or in-house PBX systems to connect computers and microcomputers together. If a local connection using a PBX or front end switch is not available, there is always dialup access with standard 103/212 modems. Data can be transferred with very simple methods, such as TYPING a file on one system and capturing it on the other system, but this gives no protection from noise and overrun of data. It is not very user friendly either. What is really needed is a protocol to accomplish file transfer reliably and efficiently.

The first obvious use of any program or protocol designed to accomplish file transfer is to be able to provide the ability to support file uploads and downloads from minis and superminis such as the VAX and PDP-11 to remote personal computers, such as the Atari 800. It should also be widely available for many different micros and mainframes. File transfer from micro to micro, as well as from a larger central host, should be possible. The command interface should be easy to learn, and require no intervention from a central site operator or other user. The many implementations of Kermit follow these lines, and all versions allow some form of transfer in either direction. More advanced versions,

such as those found on the PDP-11, DEC10/20 and VAX, offer what is known as server operation, which allow the remote (connected) Kermit system to completely control the file exchanges from their system. Since as of this writing (October 9, 1985) there are available over 160 versions of Kermit available for numerous mi-

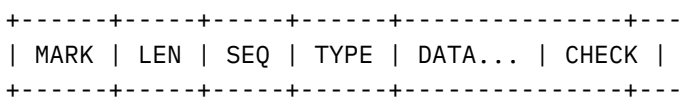
cro, mini and mainframe configurations, Kermit addresses this need quite well.

While the primary use of Kermit will likely be to support file transfer from microcomputer to mini/supermini and mainframe connections, there are many uses for Kermit for connections from mini to mini and so on.

The Kermit protocol

The Kermit protocol is designed to operate over normal asynchronous terminal lines. All data and commands are transferred with a packet oriented protocol, basically consisting of a start of packet character (normally SOH), followed by length, control, data and checksum fields. Communication is half duplex, in that for every packet sent, the sender must wait for either an acknowledgement packet (ACK) or a negative acknowledgement packet (NAK). Transmission is in ascii, with no requirements for the transmission of eight bit characters or control characters other than control-A for marking the start of a packet. All 'control' characters imbedded in the data are prefixed to convert them to printable characters, the same applying to eight bit characters if required by the characteristics of the line. Since there are many different implementations of Kermit, the protocol provides a mechanism by which the capabilities of two connected Kermits can be negotiated to allow for differences in the level of protocol support. Examples of protocol features that not all Kermits understand include data compression and transfer of file attributes.

The packet format is



where all fields consist of ASCII characters, and the char function converts a number in the range 0-94 (10) to a printable ASCII character by adding 32 (10). The MARK, LEN, SEQ and TYPE fields are one byte, the DATA field is variable in size, and the CHECK field is one to three bytes in size.
The MARK (normally control A) signifies the start of a packet. The length field tells how long the rest of the packet is. The SEQ field is used to insure synchronization used to detect lost or

duplicate packets. The SEQ number wraps around every 64 packets due to the need to encode it as a printable ascii character in the range 32 (10) to 126 (10). The TYPE field specifies whether the packet is a DATA or CONTROL packet. The DATA section is used for the actual transfer of data or informative messages from a Kermit server, this field can be up to 90 characters in length. Any character whose low seven bits fall in the range of 0 to 37 (8),

ie, char and 177 (8) is less than 40 (8), will have the value 100 (8) exclusive or'ed (xor'ed) with itself and be prefixed by a shift character, '#'. Other shift characters may be use for eight bit characters if the line characteristics require such. Data compression may also occur in the data field, this is done with yet another shift code and byte count sequence. The CHECK field is a checksum, either a one character, two character or three character CRC check; the sender computes it and the receiver must compute it and compare. A checksum mismatch will result in the receiver sending a NAK packet (negative acknowledgment) which directs the sender to resend the NAK'ed packet. The packet may be following by a terminator (likely an ascii 13). This terminator is NOT part of the protocol and is sent only to tell the receiver that a 'line' is present. Not all Kermit implementations require this; all Kermits will discard data outside of a packet in any event.

Error detection and recovery is by checksum, as noted, and by packet read timeouts. If the packet should be corrupted the checksum will be incorrect, the receiver will NAK the packet. If an expected packet never arrives within the timeout period, or if the received packet is not the expected one (as determined by the SEQ field) the packet will also be NAK'ed. There are limits as to how many times an expected packet will be NAK'ed without aborting the current operation.

Packet types

D Data
Y Acknowledgement (ACK), test may be in DATA field
N Negative Acknowledgement (NAK)
S Send initiate (Send-Init)
R Receive Initiate
B Break (EOT, end of transmission)
F File name header
Z End of file (EOF, end of current file)
E Error packet, text may be present in DATA field
G Generic SERVER command. The first character in the
data field will be a command to a server, arguments
may follow that character.
I Login, user and password follow in data field
C CWD, change working or default directory.

L Bye, Logout server
F Finish, Exit server, but do not log out
E Erase, delete files on server system
D Directory query
U Disk space usage query
T Type a file onto local kermit
R Rename file(s) on server system

K Copy file(s) on server system
W Who's logged in, as in sho sys, sy/s, dev tt
M Send a terminal message to a user
H Help, the server responds with commands it can do
Q Server status query
P Program, run a program
J Journal
V Variable, alter a Kermit setting

C Execute host command. The host command follows in
the data field.

Note that some of the generic server commands, as well as the C packet, may not be feasible for a given environment. For instance, the REMOTE LOGIN command, which sends the generic I command to the server, can only be done under systems that allow you to dial up and start a Kermit without logging in; the generic U command (disk space) is meaningless under some systems (like RSX) unless one wants the free space on the entire volume. No Kermit server will abort on receiving a packet it can't execute, it will simply send an error packet with an informative message saying it can't process the requested function.

An example of a Kermit-65 kermit telling a PRO Kermit-11 server to expect a file follows. The Kermit-65 command was "Send foo.txt"

(0)Atari sends: * S~# @-#Y(
(0)Pro sends: 0 Y~* @-#Y1~* ~T
(1)Atari sends: *!FFOO.TXTE
(1)Pro sends: #!Y?
(2)Atari sends: S"DThis is a test file#M#J
containing two lines.#M#JU
(2)Pro sends: #"Y@
(3)Atari sends: ##ZB
(3)Pro sends: ##YA
(4)Atari sends: #$B+
(4)Pro sends: #$YB

In packet zero, the Kermits exchanged information regarding their capabilities. The Atari sent an 'S' packet with the data for its

maximum packet length, default time out, number of pad characters to follow a packet (none, hence the space), use a null for padding, end of line terminator (a CR + 32), the prefix character for control characters, and a 'YES' to say the it can prefix eight bit characters with the default. It doesn't send any of the extension fields, like indicators for multi-byte CRCs, file header info etc. In packet 1, the Atari sends the filename the Pro should use for the file it creates. The Pro then sends the acknowledgement. In packet three, the Atari sends the first (and only for this file)

packet of data. Note that the sequence #M#J is a carriage return/line feed sequence with 100 (8) xored into each character. The '#' character informs the other Kermit that it must xor the next character with 100 (8). In packet three the Atari sends an EOF packet, the Pro acks it. In packet four, the Atari sends a break packet which tell the Pro that no more files (of a possibly wildcard group) are coming and the Pro Kermit acks the break packet. The Pro kermit then enters the server idle state. More specific information regarding Kermit packets and state transitions can be found in the references listed at the end of the article.

Future directions

With the advent of packet switched networks and satellite communications the Kermit protocol will likely be extended to increase efficiency over such links. The main problem is the half duplex nature of Kermit, the packet acknowledgements can take up to several seconds in transit thus drastically reducing the throughput. There are several possibilities under discussion and a standard should be appearing shortly.

Summary

With the knowledge that there are Kermit implementations for most personal computers in use it becomes apparent that the Kermit standard is well worth looking in to.

(End of protocol description)

For more documentation on what Kermit protocol is all about, see the extensive doc available from the Kermit folks at CU20B.ARPA.

In article <771@udccvax1.acs.udel.EDU>, gdtltr@vax1.acs.udel.EDU (Gary D Duzan) writes:
>
> Greetings all. I have noticed that there is a good bit of talk about posting
> good PD programs and not much actual posting. For example, I have been looking
> for Kermit-65.
This is a repost of the kermit.65, it will have the original poster's
notes and is in three packages. I do hope somebody will tell Gary and
I how to get programs out of LISTSERV, I have been able to get all kinds
of information, but no programs.
I will send the kermit in three files separate from this one.

974. kermit.65 resend

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-09 17:06:15 UTC
From: seg@pbhya.UUCP
Message-ID: <10858@pbhya.UUCP>
Source record: 117078

This is a repost of Kermit-65, with bug-fixes and enhancements in response to the feedback from the first release. The three parts are the revised documentation, following this text, and binaries for KERMIT.COM and KERMITNR.COM, exactly the way the first posting was done. Please see the documentation for a description of the changes since first release. (Yes, the infamous binary bug is fixed).

Archive maintainers: Please replace any old versions of Kermit-65 with this one.

Here's the doc:

```
-------------------------------kermit.doc--------------------------------
Kermit-65 Manual and bug list Page 1

Kermit-65 for Atari 800s

By John Dunning. Bug reports to me (JRD@Symbolics.COM) via Arpanet.
Other net users will have to find some way of getting mail to Ar-
panet, then use the above address.

Kermit-65 is a port of the kermit-65 available for Commodore frobs.
It runs on 48K Atari 800 family machines. Current version (second
release) is 3.3.

Capabilities:

File transfer, text and binary:

Without going into excruciating detail here, Kermit-65 is a fairly
complete implementation of a user side, using the KERMIT protocol.
It's been tested against Kermit-11 under RSX, and C-Kermit under
VMS and Un*x, and seems to work fine. For a description of what
the KERMIT file protocol is all about, and something about how the
it works, see the 'Kermit protocol' section at the end of this do-
cument.

Terminal emulation:

Glass tty, Vt52, or Vt100. Supports 3 flavors of screen
configuration; Atari standard screen, 80-column pannable
(40-column visible) like VTERM, and 80-column graphics, like
V10SQR. Terminal emulation modes may be used in any combination
with screen configurations, though some combinations won't work
real well; for instance trying to do full-screen Vt100-style ed-
itting when using the Atari screen is a good way to lose.

Local file management:
```

Kermit-65 includes Directory, Erase, and Rename commands, allowing the user to do most kinds of maintainance operations without leaving the program. It also allows you set set the default drive to any value 1 thru 8, so you're not stuck using a single drive for everything.

Typing at Kermit-65:

The command processor accepts command lines, consisting of a keyword, optionally some more keywords, and optional values. Things in command lines are delimited by spaces, and terminated by <CR>. At any time, you may type '?' to get a list of valid completions for the word you're typing. You need not type keywords completely; however much uniquely identifies the word you want is enough. At any time, <ESC> will attempt to complete what you've

typed so far. Note that if you've typed a word, but haven't hit a <space> or <ESC> yet, so that the cursor's at the end of the word, '?' will tell you that there's only the one possibility. Hit a space, then '?', for a list of possibilities for the next word. Some commands are 'defaults' in the sense that if you type something non-unique, and hit escape, and one of the possibilities is a 'default', it will win over the other possibilities. One example of this is 'Send'.
Example: The following illustrates a typical interaction between you, the user, and Kermit-65. The stuff that Kermit types (prompts, echos of partial commands, and help) is on the left, stuff typed by the user is in the middle, and commentary is on the right.

Kermit types: You type: Comments:

"Kermit-65>" Kermit prompts.

"s?" User starts typing a
command starting with
"s", then hits "?" for
help.

"Keyword, one of the following: Kermit prints possible
set show for "s"...
send
Kermit-65>s" and reprompts, with the
partial command.

"et?" User finishes the "set"
command, and asks for
help again.

"Keyword, one of the following: Kermit prints the (one)
set possible completion.
Kermit-65>set"

" ?" User hits a space, then
asks for help again.

"Keyword, one of the following:" Kermit prints possible
(various subcommands of 'set' here) completions for words
that can follow "set"

Kermit-65 Manual and bug list Page 3

Kermit-65 commands:

Bye
Tells the kermit on the other side to log out, and ex-
its Kermit-65.

Finish
Tells the kermit on the other side to exit server
mode, but stay logged in.

Connect
Puts Kermit-65 in terminal mode, using whatever param-
eters are currently set for Terminal and Screen confi-
guration. See 'Set Terminal' and 'Set screen' for
more details.

Quit
Exit from Kermit-65 back to Atari DOS.

Exit
Same as Quit.

Get
<file spec>
Ask the kermit on the other side to send the named
file, using whatever file and protocol parameters are
currently in effect. See 'Set' for more details.
Note that <file spec> may be wildcarded; assuming the
serving kermit allows that. In that case the serving
kermit may send several files; Kermit-65 will try to
receive all of them.

Send
<file spec>
Send the named file to the kermit on the other side.
If the file spec is wildcarded (using DOS FMS wildcard
rules) all matching files are sent. In the latter
case, the Kermit on the other side should be in Server
mode, so that it can deal with a whole sequence of in-
coming files.

Receive
<file name>
Attempt to receive into the named file. Assumes the
other kermit is already trying to send it. If no file
name is given, Kermit-65 will attempt to get the name

from the file-header information coming from the other side. This is the command to use after telling the other kermit "Send <something>".

Kermit-65 Manual and bug list Page 4

Set
Baud
(50..9600)
Sets baud rate on the comm port to the supplied value.

Parity
Even, Odd, Mark, Space, None
Sets specified parity for the comm port. See the Atari 850 man for more details on the behaviour of the various parity options.

Word-size
Seven, Eight
Set frame size used for comm port. The default is eight-bit. The preferred value for this depends on what the parameters of the serial line are set to on the other side. In my experience, older systems will tend to use seven-bit configurations, more modern ones will tend to use eight-bits. If you're not sure, it usually works to use eight-bit.

Default-disk
<1..8>
Sets the default disk for all file operations. Legal values are 1 to 8, inclusive.

Rs232-registers
<16-bit hex number>
Directly sets some of the the values used when configuring the serial port. Specifically, the high byte is used as the AUX1 parameter for the XIO 38 (configure translation and parity) and the low byte is used as the AUX1 parameter for the XIO 36 (configure baud rate and word size). This allows settings to be used that aren't covered by the supplied keywords in Baud, Parity, and Word-size.

Debugging
Off, Terse, Verbose
Turns on/off various debug msgs strewn around in the code.

Eight-bit-quoting
On, Off
Turns on/off eight-bit mode quoting in the kermit protocol. The default is off.

File-warning
On, Off
When this mode is on, Kermit-65 will refuse to overwrite files when receiving. When it attempts to receive a file that's already present, it will alter the filename of the incoming file so as not to overwrite the old version. The algorithm for altering the filename is to replace the extension field of the name with a 2 digit hex number, and retry. If the file still exists, the number is incremented. This repeats until a free name is found, or the extension reaches "FF", at which time the receive is aborted. (I think it's never possible to get that far anyway, as you can't put 256 files on one of these disks)

File-type
Atascii
This is a standard atari text file, and is the default mode. End of line is signalled by the ATEOL character ($9B). When sending, other ATASCII characters are translated to their ASCII equivalents, ie ATTAB ($7F) -> Tab ($09), ATRUB ($7E) -> Rubout ($7F). The file header info generated indicates that a text file is being sent. Receiving one does the opposite transformation.

Ascii
Files are sent/received as ordinary ascii-text. Line terminators are assumed to be CR ($0D) followed by LF ($0A), and are handled in the usual kermit fashion. No translation of data happens. This mode isn't the right thing for regular old text files, but is useful for sending around files that are output in plain ascii from various utilities. For example, I have a word processor program which produces formatted output files in ascii, intended to be dumped directly to a printer. This mode gets them over to my pdp-11's print spooler.

Binary
Data is sent in kermit binary form, no line terminators etc.

Flow-control
On, Off
Turns ^S^Q flow control on/off for the incoming line. See 'Com port handling', below, for more details.

Ibm-mode
On, Off
Turns on/off 'IBM mode'. This is apparently a standard thing in kermit implementations, made necessary by the wierditudes designed into the blue equipment. This code has been left as is, so it's got some chance of working, but has not been tested.

Local-echo
On, Off
Controls echo mode in terminal emulator. Default is off.

Send
End-of-line, Padding, Timeout, Pad-char, Quote-char, Eight-bit-quote, Packet-length
Sets one of the listed parameters for the transmitting side of the kermit protocol. Padding, timeout (seconds), and packet-length are in decimal, the others (character codes) are in hex. This command is primarily used when talking to a kermit that can't or won't use the standard set of protocol characters for beginning-of-frame, end-of-frame, etc. As such, it's not generally useful, at least I've never seen a kermit that required it. There are things that might come in handy, though. For instance, if you've got an exceptionally dirty phone connection, you might want to set the frame size down from the default of 94. In that case, you might say "Set Send Frame-size 30". Note that Send parameters can be reset by the other Kermit sending one of the kinds of packets that request certain values, so you may have to tell him directly, to get the effect you want.

Receive
All parameters settable same as 'Send'

Screen-driver
Atari
The standard 24x40 Atari screen driver. This mode does its output to the internal E: device. This isn't very useful for complicated things, but is supplied in case kermit's running someplace where there's not enough memory to do anything better. (Besides, I had to have all the code for it lying aound for other reasons, so why not?)

40-column
A 24x80 screen, using the character CTIA mode. Since that mode only allows 40 visible columns, the screen is pannable left to right, allowing any 40-column

chunk to be displayed. The terminal code will attempt
to keep the cursor visible by panning around while
output is happening. You can also pan manually using
the Start and Select keys. In this mode, reverse- vi-
deo output works, but none of the other highlighting
types.

80-column
A 24x80 screen, using the hi-res (320 bits/raster)
graphics CTIA mode. In this mode, both reverse video
and underlining are supported. This is the default
setting for screen mode.

Terminal-emulation
Vt100, Vt52, None
Sets the terminal emulation mode to the specified va-
lue. The default is Vt100.

Show
any of the same keywords as 'Set', or 'All'
Display the value(s) of the specified thing(s). 'All'
displays the values of everything in sight.

Status
Dump various goodies about the last file transfer; characters
in, out, naks, timeouts etc.

Directory [<filespec>]
Display a directory list from the default drive. <filespec>
is optional, if omitted, it defaults to "*.*".

Rename <from-filespec> <to-filespec>
Does a rename operation on files on the default drive. Either
filespec may be wildcarded, in which case the rename operation
happens according to the rules described in the ATARI OS FMS
documentation.

Erase <filespec>
Erases files on the default drive. Filespec may be wild-
carded, in which case the erase operation happens according to
the rules described in the ATARI OS FMS documentation.

Save
Dump Kermit-65 parameters such as screen settings, send/re-
ceive parameters, etc to an init file "KERMIT.INI" on the
default disk.

Restore
Read parameters from "KERMIT.INI" back into the running
Kermit-65.

Help
Gives a summary of the above command list.

Other interesting things about terminal modes:

Depending on what terminal you're using, there are several things which may be of interest. In 40 or 80 column modes, there's a status line under the 24 data lines. It displays what special keys are active, and the status of the comm port. In 40 column mode, Start pans the screen right, and Select pans left. In both 40 and 80 col modes, Option is used to get the kermit's attention. In Atari mode, c-Y is used instead.
Once you have kermit's attention, it wants a character; one of:

C Break the connection
B Send a break (approx 1/4 sec)
S Display status

Function keys:

Kermit-65 can generate function key sequences ala VT100. The current function key bindings are as follows: (c-sh- means control-shift...)
c-sh-0..c-sh-9 keypad 0 thru 9
c-sh-. keypad dot
c-sh-backspace keypad minus
c-sh-, keypad comma
c-sh-return Enter
c-sh-q..c-sh-r PF1..PF4
c-sh-- Up arrow
c-sh-= Down arrow
c-sh-< Left arrow
c-sh-> Right arrow

Other key bindings for things not on the Atari keyboard:
sh-< { (left brace)
sh-> } (right brace)
sh-backspace ~ (tilde)
c-sh-backspace, or c-7 ` (backquote)

Kermit-65 Manual and bug list Page 9

These key bindings aren't quite what I had in mind, but the OS rom won't let me get at all the control-shift keypresses, so they'll have to do for now. I encourage any feedback about how these feel. I've been using them for a while now, and they don't seem as bad as I expected. In particular, they work passably well when using EDT (I'm typing this document with it), which I think is an indication that they're useable, as it's a real keypad hog.

Other special keys:

The Atari key (/|\ on 800 vintage dinosaurs like mine, |/| on newer 800XL vintage equipment) behaves in a special fashion when

using Kermit-65. It toggles a flag that causes input from the comm port to be held up, rather than processed as soon as possible. This is useful for causing the screen to hold up temporarily when in terminal mode. If flow control is enabled, it behaves in the expected fashion; it'll tell the other side to shut up until you press the Atari key again, to let pending input be processed again.

The status line:

When in 40-column or 80-column terminal modes, there's a 25th line below the usual 24 lines of terminal screen. This is the status line. It will look something like this:

K65: Option + o v Rs ok

There are several interesting things displayed here: At the left side, after "K65", is a list of which special keys (option, select, start) are active at the moment. If you press Option, this will change to a prompt for the special characters that can follow Option. In column 22 ('+', above) will appear '+' or '-', or space. This indicator shows you the state of the flow-control logic; + means incoming traffic is enabled, - means it's disabled. Note that it when flow-control is turned on (see commands, above) this flag will toggle back and forth between + and - as the flow-control logic does its thing. If flow-control is turned off, it will just sit on + all the time. Column 24 ('o' above) will contain a blot if comm-port reading is suspended, space otherwise. In column 26, ('v') above, is the caps lock indicator. It will display an up-arrow if caps are locked, or a down-arrow if not. In column 32 is a message describing the last known state of the comm port.

Com port handling:

In its current configuration, Kermit-65 expects to talk thru an Atari 850. In principal, that ought not to be a restriction, but I (JRD) only have an 850 to test with, and don't know what requirements there are for other devices. I've tried to be scrupulous about sticking to the documented interfaces to things, however, so I'd expect any driver that adheres to the spec to work.

The port's opened and closed a lot; you'll hear it, as I've left the 'noisy bus' option turned on. It uses page 6 ($600) as an IO buffer. Since that's only 256 bytes, there's the possibility of overruns at high baud rates. When flow-control's on, Kermit will attempt to shut off the other side when it sees more than 50 bytes pending; it will turn it back on when there's less than 10.

As of this writing, Kermit-65 has been out in the field for a while, and seems to work ok with things other than 850s. One word of caution; I've gotten some feedback to the effect that the default timeout values I chose are too short for reliable operation at low baud rates. I've decided not to change the defaults, as you can easily change them in your KERMIT.INI file, and because most folks seem to have access to 1200 bps modems and things these days. However, if you're running at 300 bps and seeing reliability problems, try pushing the timeouts up to say 15 sec or so.

Other ramblings:

Version 3.3 loads at $2D20, and uses up thru about $B000. That means it'll only run on 48K machines. It appears to run fine on XL and XE equipment, but most of my testing has been on an 800, so there may be some problems. BTW, that load address was chosen because the latest version of DOS XL for Indus GT's uses up thru $2D14 when it's configured for two drives, and the 850 driver is loaded. Older versions of DOS XL take up less memory, as does DOS. I don't know what the requirements are for things like Spartados. If anyone comes up with a conflict, let me know, and I'll assemble you a version that's org'ed somewhere else.

On XLs and XEs, kermit-65 will require that the machine be booted with BASIC disabled, as it's not yet bright enough to detect that that's where it is and map out the cart. (if anyone knows how to do that, and feels like saving me some work...) Kermit-65 is available in 'bare' form, or with an autoloader for the 850 driver prepended to it. The bare version requires that you load whatever rs232 driver you're going to use first, then run kermit. The autoloader equipped version does that for you.

Kermit-65 Manual and bug list Page 11

For those of you who have YAU (posted separately) the byte count and checksum values for KERMIT.COM and KERMITNR.COM respectively are 24622, #x5F17; and 24408, #x1560.

Kermit-65 Manual and bug list Page 12

Credits

I blew it when distributing the first version of this document, and forgot to include this section. Mea culpa.

Many thanks to my beta testers, in particular Marshall Abrams, for his patience in dealing with initial versions of this thing, and for aid in making this document clearer. Thanks also to John Sangster for helping nail down my obscure terminal emulator bugs, and miscellaneous kibutzing. (Sorry John, I still haven't gotten in the key defining util. Maybe next version).

Kermit-65 Manual and bug list Page 13

Bugs and misfeatures:

There's no way to set the comm port to other than R1:. Does anyone care?

The help processor doesn't deal properly with upper-case, and thinks there are no completions.

Vt100 mode is missing still missing insert/delete character.

Blinking fields, bright fields, double-high, double-wide, and 132-col mode are not supported. (Reverse vid and underline are)

There's currently no way to set the screen colors.

It's possible to confuse yourself by hitting c-1 in terminal mode, as my screen drivers ignore it, but Atari's doesn't. You're fine until you break the connection, then everything appears to wedge up.

Flow control for the incoming side of the connection isn't implemented. This can cause problems when trying to send at high baud rates to a host that's got a stupid serial driver, or a small typeahead buffer.

The part of the command parser that deals with pathnames is completely bankrupt (that's what I get for using old code), and doesn't work properly unless it's told that a null pathname is legal. The result of all this is that when entering pathnames and asking for help before entering any data, it will tell you "input file spec or confirm with <cr>". Pay no attention to the man behind the curtain; you really do have to put a pathname in there for anything to happen.

Kermit-65 Manual and bug list Page 14

Bugs fixed for v 3.1

Save and Restore now actually do something, instead of being effectively no-ops.

Rename and Erase commands are now implemented. This means that virtually all file operations one cares about (while up/downloading) can be done without leaving Kermit.

File-warning mode has been fixed so that it really does something useful, instead of just bitching about the file conflict.

The pathname parsing substrate has been installed, so that defaulting and merging can be done in a reasonable fashion, instead of by ad hoc kludgery.

The screen hacking code has been cleaned up a good bit, so as not to be continually clearing the screen when doing transfers.

Logging code has been added to tell the user what files are being sent and received.

Status and help commands in terminal mode are now working.

The directory command now takes an optional filespec parameter.

Bugs fixed for v 3.2

Binary mode now works again. (Sheesh!)

Rename and Erase routines now make sure the comm port's closed before attempting to hack the disk.

The user interface has been cleaned up some; all numeric values other than character codes and some debugging info is now displayed and entered in decimal, rather than hex.

Bugs fixed for v 3.3

Fixed a dumb bug in terminal code that caused graphics mode to be entered at unexpected times.

Kermit-65 Manual and bug list Page 15

Fixed file reading code so as not to get confused and generate an extra byte when running under non-standard things like SpartaDos.

Cleaned up Directory code; using new pathname-mapping substrate.

Added support for wildcarded pathnames in Send code.

Fixed packet-dumping debug code to not mask off top bit of char, and quote everything to keep from interpreting screen hacking chars.

Fixed init code to look for an init file on D1, and read it if found.

Fixed flow control code so as not to wedge up unexpectedly.

Re-enabled the suspend-input capability, using the Atari (/|\) key.

Break (Option-B) in terminal mode has been fixed.

Cleaned up the font used in 80-col mode.

Removed Speedscript file type, as Speedscript apparently just uses plain vanilla text files. Changed default file type to Atascii.

Added caps lock functionality, similar to standard Atari kbd driver.

Fixed a bug in terminal mode that was trashing the stack.

Kermit-65 Manual and bug list Page 16

The Kermit Protocol

The following a brief description of the Kermit file protocol, excerpted from one of the many documents kicking around. If you already know what it is, or don't care, skip this section.

The Kermit protocol allows many (if not most) types of computer systems to effect, at minimum, error free file transfer with other systems and microcomputers over asynchronous lines.

Introduction

With the widespread use of personal computers the need for file exchange between systems has become of foremost concern among users and managers alike. There are many commercial products available which meet this need, some of which may offer more advanced functions such as transparent record oriented file access. Networks that do this, such as DECnet, can be expensive, and if your computer or microcomputer is not on the network your needs won't be met. Transfer of files with removable disks can work, but generally only when the computers are of the same type, it's not very useful when the systems are removed in location. Rarely will a larger mini or supermini be able to read a microcomputer's disk.

A more realistic approach, from both cost and convenience, is to find a way to use ordinary telecommunications and/or in-house PBX systems to connect computers and microcomputers together. If a local connection using a PBX or front end switch is not available, there is always dialup access with standard 103/212 modems. Data can be transferred with very simple methods, such as TYPING a file on one system and capturing it on the other system, but this gives no protection from noise and overrun of data. It is not very user friendly either. What is really needed is a protocol to accomplish file transfer reliably and efficiently.

The first obvious use of any program or protocol designed to accomplish file transfer is to be able to provide the ability to support file uploads and downloads from minis and superminis such as the VAX and PDP-11 to remote personal computers, such as the Atari 800. It should also be widely available for many different micros and mainframes. File transfer from micro to micro, as well as from a larger central host, should be possible. The command interface should be easy to learn, and require no intervention from a central site operator or other user. The many implementations of Kermit follow these lines, and all versions allow some form of transfer in either direction. More advanced versions,

such as those found on the PDP-11, DEC10/20 and VAX, offer what is known as server operation, which allow the remote (connected) Kermit system to completely control the file exchanges from their system. Since as of this writing (October 9, 1985) there are available over 160 versions of Kermit available for numerous mi-

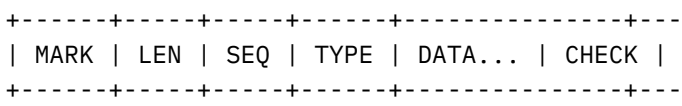
cro, mini and mainframe configurations, Kermit addresses this need quite well.

While the primary use of Kermit will likely be to support file transfer from microcomputer to mini/supermini and mainframe connections, there are many uses for Kermit for connections from mini to mini and so on.

The Kermit protocol

The Kermit protocol is designed to operate over normal asynchronous terminal lines. All data and commands are transferred with a packet oriented protocol, basically consisting of a start of packet character (normally SOH), followed by length, control, data and checksum fields. Communication is half duplex, in that for every packet sent, the sender must wait for either an acknowledgement packet (ACK) or a negative acknowledgement packet (NAK). Transmission is in ascii, with no requirements for the transmission of eight bit characters or control characters other than control-A for marking the start of a packet. All 'control' characters imbedded in the data are prefixed to convert them to printable characters, the same applying to eight bit characters if required by the characteristics of the line. Since there are many different implementations of Kermit, the protocol provides a mechanism by which the capabilities of two connected Kermits can be negotiated to allow for differences in the level of protocol support. Examples of protocol features that not all Kermits understand include data compression and transfer of file attributes.

The packet format is



where all fields consist of ASCII characters, and the char function converts a number in the range 0-94 (10) to a printable ASCII character by adding 32 (10). The MARK, LEN, SEQ and TYPE fields are one byte, the DATA field is variable in size, and the CHECK field is one to three bytes in size.
The MARK (normally control A) signifies the start of a packet. The length field tells how long the rest of the packet is. The SEQ field is used to insure synchronization used to detect lost or

duplicate packets. The SEQ number wraps around every 64 packets due to the need to encode it as a printable ascii character in the range 32 (10) to 126 (10). The TYPE field specifies whether the packet is a DATA or CONTROL packet. The DATA section is used for the actual transfer of data or informative messages from a Kermit server, this field can be up to 90 characters in length. Any character whose low seven bits fall in the range of 0 to 37 (8),

ie, char and 177 (8) is less than 40 (8), will have the value 100 (8) exclusive or'ed (xor'ed) with itself and be prefixed by a shift character, '#'. Other shift characters may be use for eight bit characters if the line characteristics require such. Data compression may also occur in the data field, this is done with yet another shift code and byte count sequence. The CHECK field is a checksum, either a one character, two character or three character CRC check; the sender computes it and the receiver must compute it and compare. A checksum mismatch will result in the receiver sending a NAK packet (negative acknowledgment) which directs the sender to resend the NAK'ed packet. The packet may be following by a terminator (likely an ascii 13). This terminator is NOT part of the protocol and is sent only to tell the receiver that a 'line' is present. Not all Kermit implementations require this; all Kermits will discard data outside of a packet in any event.

Error detection and recovery is by checksum, as noted, and by packet read timeouts. If the packet should be corrupted the checksum will be incorrect, the receiver will NAK the packet. If an expected packet never arrives within the timeout period, or if the received packet is not the expected one (as determined by the SEQ field) the packet will also be NAK'ed. There are limits as to how many times an expected packet will be NAK'ed without aborting the current operation.

Packet types

D Data
Y Acknowledgement (ACK), test may be in DATA field
N Negative Acknowledgement (NAK)
S Send initiate (Send-Init)
R Receive Initiate
B Break (EOT, end of transmission)
F File name header
Z End of file (EOF, end of current file)
E Error packet, text may be present in DATA field
G Generic SERVER command. The first character in the
data field will be a command to a server, arguments
may follow that character.
I Login, user and password follow in data field
C CWD, change working or default directory.

L Bye, Logout server
F Finish, Exit server, but do not log out
E Erase, delete files on server system
D Directory query
U Disk space usage query
T Type a file onto local kermit
R Rename file(s) on server system

K Copy file(s) on server system
W Who's logged in, as in sho sys, sy/s, dev tt
M Send a terminal message to a user
H Help, the server responds with commands it can do
Q Server status query
P Program, run a program
J Journal
V Variable, alter a Kermit setting

C Execute host command. The host command follows in
the data field.

Note that some of the generic server commands, as well as the C packet, may not be feasible for a given environment. For instance, the REMOTE LOGIN command, which sends the generic I command to the server, can only be done under systems that allow you to dial up and start a Kermit without logging in; the generic U command (disk space) is meaningless under some systems (like RSX) unless one wants the free space on the entire volume. No Kermit server will abort on receiving a packet it can't execute, it will simply send an error packet with an informative message saying it can't process the requested function.

An example of a Kermit-65 kermit telling a PRO Kermit-11 server to expect a file follows. The Kermit-65 command was "Send foo.txt"

(0)Atari sends: * S~# @-#Y(
(0)Pro sends: 0 Y~* @-#Y1~* ~T
(1)Atari sends: *!FFOO.TXTE
(1)Pro sends: #!Y?
(2)Atari sends: S"DThis is a test file#M#J
containing two lines.#M#JU
(2)Pro sends: #"Y@
(3)Atari sends: ##ZB
(3)Pro sends: ##YA
(4)Atari sends: #$B+
(4)Pro sends: #$YB

In packet zero, the Kermits exchanged information regarding their capabilities. The Atari sent an 'S' packet with the data for its

maximum packet length, default time out, number of pad characters to follow a packet (none, hence the space), use a null for padding, end of line terminator (a CR + 32), the prefix character for control characters, and a 'YES' to say the it can prefix eight bit characters with the default. It doesn't send any of the extension fields, like indicators for multi-byte CRCs, file header info etc. In packet 1, the Atari sends the filename the Pro should use for the file it creates. The Pro then sends the acknowledgement. In packet three, the Atari sends the first (and only for this file)

packet of data. Note that the sequence #M#J is a carriage return/line feed sequence with 100 (8) xored into each character. The '#' character informs the other Kermit that it must xor the next character with 100 (8). In packet three the Atari sends an EOF packet, the Pro acks it. In packet four, the Atari sends a break packet which tell the Pro that no more files (of a possibly wildcard group) are coming and the Pro Kermit acks the break packet. The Pro kermit then enters the server idle state. More specific information regarding Kermit packets and state transitions can be found in the references listed at the end of the article.

Future directions

With the advent of packet switched networks and satellite communications the Kermit protocol will likely be extended to increase efficiency over such links. The main problem is the half duplex nature of Kermit, the packet acknowledgements can take up to several seconds in transit thus drastically reducing the throughput. There are several possibilities under discussion and a standard should be appearing shortly.

Summary

With the knowledge that there are Kermit implementations for most personal computers in use it becomes apparent that the Kermit standard is well worth looking in to.

(End of protocol description)

For more documentation on what Kermit protocol is all about, see the extensive doc available from the Kermit folks at CU20B.ARPA.

I had the same problem with Star Raiders. Like you, I got a replacement
which did the same thing. Also an 800. No idea what the problem is.

I've done this with a 400 and 800. I just connected the SIO port on each on to the back of the disk drive (810). It worked, as long as they didn't both do IO at the same time. However, the SIO cables carry +5 volts, so even if you turn the power switch on one machine off, or even unplug it, it will remain on, powered by the other's power supply. It's kind of strange to flip the power switch on and off, and have nothing happen. This does put a strain on the powe supply that is still connected, and is probably bad. I never did it for very long, as I just wanted to see if it worked. I think that having both machines' power supplies on could also be bad, as they might output slightly different voltages, and they would each try to pull up or drop the other's voltage. In other words, yes, it'll probably work, but I wouldn't recommend it for any length of time. Also, try to turn them on simultaneously, to avoid undue strain on a single power supply.

Not that I know anything about the subject (I'm queasy about frying my hardware), but wouldn't it make more sense to make SURE you don't turn on both computers simultaneously? I would think that the proper way to do this was to turn on Computer A, let it load DOS, then when that's done, turn on computer B, and let it load DOS...

By the way, wasn't there a company that makes a multicomputer/pherepheral switching box for the Ataris, to handle situations like this (Ten Ataris, running all at once and sharing hard drives, printers, etc.)?

About chaining two atari's to the same disk drive... I also have two (a 400 and a 65XE) and, playing two-man games on the two with separate TV's sounds real interesting. It would be good to be able to load each (in turn) from the same disk (I only have one as well). To do this, I would suggest just cutting the 5V line in one of the cables.

On a different subject: I have been noticing hard disk drives available for IBM PC's in mail-order catalogs for as little as $199 for 10MB. It seems an interesting thing to do might be to adapt one of those to the atari. I don't have the slightest idea how to do it, but am an experienced hardware designer, and have done a lot of 6502 assem lang as well. Anybody want to team up? I live in eastern Mass, if that matters.

Yes, it probably IS bad. I have a friend who did what you describe, with two 800XL's and a 1050, and ended up destroying (burning out, somehow) both of the 800XL's. As in, beyond hope of repair. Brett, you got LUCKY!

A few years ago, less than a year after I got my 800, I had a similar problem with Star Raiders. Later (after I had the machine about a year) it would often lock up on other programs, and even not come up at all (I would just see a green screen). I took the machine to a local "authorized Atari service center" (Rex TV Repair), but they couldn't find the problem. At that time, Atari operated their own service center somewhere north of where I live around here (Rolling Meadows?). They _did_ find and fix the problem (bad OS chip or some other bad chip... can't remember now). It seems that when chips start going bad, they will work OK until they warm up some, and then start doing strange things, or just stop working altogether. I still have the same Star Raiders cart, and it still works (2 Atari 8-bit machines later!).

983. Problem with Atari's new XF551 DS/DD disk drive

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-11 01:30:08 UTC
From: kevin@voder.UUCP
Message-ID: <3075@voder.UUCP>
Source record: 117087

I read something recently which points out a possibly serious problem
for some users of Atari's new XF551 disk drive. This is from an article
published in the March '88 newsletter of the Bay Area Atari Users Group
(BAAUG), I should point out that I do not own an XF551 and haven't been
able to confirm this problem but the article sounds correct.

When non-Atari users buy 5 1/4-inch floppy disks they have to purchase
either soft or hard sectored disks depending on their drive. If you look
at the disk you will see a small hole in the envelope next to the large
center hole on the side of the write-protect notch. This is the index hole.
If you now rotate the disk inside its envelope a small hole in the mag-
netic medium will appear. If the disk is soft sectored there will be one
hole, if hard sectored their will be several, usually 10 or 16 depending
on the number of hard sectors it uses. Soft sectored disks use this index
hole as the starting point for the software created sectors when formatting
a disk. Hard sectored disks use the holes to mark where each sector starts.
Atari users don't have to worry about this as neither the 810 or the 1050
drive have the LED sensor which reads this index hole(s) so they can use
any type of 5 1/4-inch floppy disk.

But the XF551 does read this index hole. If you flip the disk over, like
if you were going to write to the back side of the disk, the index hole is
now on the wrong side of the disk and the index sensor will be unable to
read it so you cannot write to the disk when it's in upside down.
So what? It's a double sided drive, you're already writing to both sides
of the disk so why turn it upside down? Well, what if you've got Print Shop?
Print Shop REQUIRES you to insert the disk upside down so it can read the
back side, but in an XF551 YOU CAN'T!. Plus, Atari 8-bit software is hard
enough to find as it is and when you do it's usually on the BACK side of a
Commodore disk! These disks will not work in an XF551!

Seems that this makes the XF551 a good second drive but not much good if
you've got a lot of 'flippy' software, unless you modify the drive so you can
switch the index sensor on/off manualy. If anyone has an XF551 I would
appreciate it if they could confirm or disprove this.

Gentlemen,

For those of you playing Phantasie by SSI, I may have some advice which will save you considerable headache near endgame.

To begin with, you *MUST* have at least rev 1.3 of the software. If you find yourself in the Astral Plane in the frame below Olympus and can't get into the dungeon there, take a look at the River Styx. Does it go all the way across the screen from left to right? On my Atari, it only went halfway and I scooted around the left hand side direct to the dungeon I could see. Unfortunately, you *MUST* cross the river via the Boatsman Charon in order to get into said dungeon. Otherwise the game will hang with no chance for recovery.

After many conservations with Bonnie at SSI (and sending my disks back four times), I finally got something that worked. You can fix this yourself if you have rev 1.3 by backing up your characters to another disk via the normal method provided. The only catch is when it asks for disk #4, insert the ORIGINAL, not your play disk. This resets all the map info you've gained throughout the game, but is a small price to pay to finish it off.

If anyone needs additional clarification, please contact me directly.

On a separate issue, does anyone have any games they have finished that you might be willing to sell (originals only please)? If so, drop me a list and I will see if I'm interested in anything.

Best regards,

Michael A. Curtis
Prime Computer, Inc.

I can suggest a potential solution to this potential problem.

Suppose the 551 used soft-sectoring when in 810 or 1050 mode, and
hard-sectoring when in 551 mode.

The 551 would ignore output from the LED and thus be fully backward-compatible.

Gary, I tried that and he mailer barfed and threw my "please send me both" message back at me. So I'll post it HERE: "please send me BOTH of your programs whose names appear above under 'Subj:' !"

> ...problems with our mail system ...

"Incoming" to you, anyway, there sure are. Hope "outgoing" is better.

Perhaps you could UUencode, then text-edit the resulting text file, break it into smaller text files, post 'em, and let us re-paste 'em back together on the receiving end? Your postings seem to be successful.

(Incidentally, they must be HUGE files; all five Kermit65-related files were put up as ONE humongous posting, 'way back when. Is it a local limit on your machine, perhaps? I'm no net.genius, so I may be wrong...)

> ...files were ARCed and uuencoded ...

Uh-oh. I don't know how to un-ARC... Well, one thing at a time I guess...

I do believe ICD's MIO interface package is supposed to let you
hook up "standard SCSI controller" hard disks to the 8-bit Atari. I
agree, it would be terrific if it works, because then it's a (relatively)
cheap source of mass storage. Unfortunately, I don't know anything about
SCSI-compatability, except that it's claimed. Any information you get
would be appreciated by a *lot* of us here, I believe.

991. ANALOG Magazine

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-14 13:25:20 UTC
From: lazear@GATEWAY.MITRE.ORG
Message-ID: <8803141325.AA05302@saturn.mitre.org>
Source record: 117095

A phone call to the new Beverly Hills offices of ANALOG brought promises that the April issue will be mailed this week, with a letter explaining the latest hassle. All subscriptions will be extended by 3 weeks as well. We'll see.
Walt (Lazear@MITRE.ARPA)
ps - I have no connection with ANALOG other than as a subscriber for many years.

True. I own the ICD MIO (1 Meg), and it does support SCSI hard ,drive
controllers. However, this is not the IBM standard controller. You can use
a normal IBM type drive, but you must have a special SCSI controller card,
which is more expensive (though one controller can usually run 2 drives).
Keep in mind that you will also need a case, power supply, special cables,
and a fan. ICD offers complete SCSI setups for anyone who is interested.

ANALOG is back. I just looked in my mail box and here it is!

On page 4 is a editoral by Lee Pappas and it just repeats the things
he said in the interview that was posted to this group. It starts off with:

"Hey, long time, no see."

The editorial never mentions who bought ANALOG just say "under new ownership."
But on the bottom of page 1: "ANALOG Computing is published monthly by
L.F.P. Inc."

It is 96 pages long and is now printed on a glossy paper. But it still isn't
bound, just the usual ANALOG staple.

It features a Action! game, a machine language game (they are printing the
source code for machine language games again) and a few BASIC programs.
They are still running the video games section for Atari, Sega and
Nintendo. There is a article by Matthew Ratcliff called "Then and now"
and it is only about the 8-bits. History is given and the future is
guessed at. For those who don't know, Matt is a EXPERT on the 8-bits.

So ANALOG is back, everyone should be getting their issues soon.

I believe that was Supra back in early 83 or so announced such a product.
I don't believe that it was ever sold commercially. At least I have, to date
never heard of anyone who actually purchased one. It was aimed more at
the school market where it would have been especially effective.

----------------------------
I have good news! ANALOG is mailing the April issues! How do I know?
I just received mine this past Saturday (3/12)!

Yes, ANALOG has been bought by a bigger company, L.F.P. Inc, which
(I guess many people know now) is, I have read on Delphi, owned by
Larry Flynt of Hustler fame ("infame?"). The content looks to be
about the same, although the mag. seems to have shrunk a bit;
there seem to be at least one fewer regular columns. But given the
problems that the ANALOG staff has had, I'm willing to give them a
while to get things back to normal. To me at least, it looks very
much the same. There seems to be the usual complement of type-in
programs, including part 2 (the compiler) of "The Wizard" text-
adventure construction package. Also, there is the 1st in a
series of 3 articles (in the "Bits and Pieces" series of h/w articles)
about connecting one 8-bit to another, to use as a printer buffer
(I guess old 8-bits are cheaper than printer buffers?), but it's a
very general look at Atari SIO etc.

The arrival of this "long-awaited" issue made my day!

I belong to a user group here in Halifax,
The Nova Scotia Atari Computer Users Group
and we have an on-going project with the local Children's Hospital. We had
arranged to obtain an Atari system, complete with Drive to donate to them.
We are still working with the Hospital's Staff and others to provide additional
items for them.
We would like to obtain PD software which is educational in nature and also
games of a non-violent type. This lets out most of the standbys, like Millipede
and Asteroids clones and equivalents, even some Adventures. They rejected
Hitchhikers Guide to the Galaxy.
Would anyone like to suggest software that would be classed under these
categories? Thanks. As for the PD educational and games, if someone would
also suggest where we might obtain them, ie bbs's preferably in the east
coastal regions of the US or Midwest. or other users groups.

I have been known to call even to California. However we need to know the
names of these programs, and what kind, ie educational or whatever and if
educational, which age/grade level it would fit under. The kids at the
Isaac Walton Killiam Children's Hospital will be most appreciative.
Thanks for reading this message.

George Seto - Using a friend's account. Oh yes, please reply via mail on the

Okay, netsters, here's an idea for you. Many of my computer buddies used to use a "notch punch" to create a "write-permission notch" on the "other" edge of a single-sided disk, so that they could "convert" them to double-sided disks and write to the back of the media.

Since it's the presence or absence of an index hole in the disk SLEEVE, rather than the rotating MEDIA, it seems to me it should be possible to punch a second set of index holes in the SLEEVE, in the "same place on the other side of the central hole," so that when the disk was flipped over there'd still be an index hole in line with the LED sensor in the drive. What say, tech hackers?

It seems to me that this would be a better solution than disabling the drive hardware hole-sensor, because isn't that used for TIMING, and mightn't bypassing it screw up one's disk reads and writes?

As far as how to actually do this, a friend of mine has suggested everything from "a real thin hole punch that could slip between the sleeve and the media" (after all, no data is stored, as I understand it, any closer to the disk center than the index hole, so if you scratch it, so what), to "take the sleeve apart, punch it, and put it back together."

Maybe if we all b*tch loudly enough (letters, petitions, etc.) we could get disks MANUFACTURED with two sets of holes in the sleeves? Betcha a cookie the "flippy" software makers will come out with them that way sooner or later; maybe we could make it "sooner" and save everybody a whole mess o' annoyance!

I'll be very interested to hear what the Net has to say about this one.

Well, you could always inspect those 5.25" disks when you first buy them, and
if they don't have the hole, you can use a notebook "hole-puncher" to do the
job... I use one for making my printouts fit in my 3-ring binder, and I would
think it'd work on floppies just fine. The only thing is, you would
probably do it BEFORE you format the disk, so that any damage/disturbance
done (if any) is negated.

>Maybe if we all b*tch loudly enough (letters, petitions, etc.) we could get
>disks MANUFACTURED with two sets of holes in the sleeves? Betcha a cookie the

Aren't these already avaliable? Can't you look at the packaging for the
disks and see if they're "double-sided/timing hole" disks?

From: dennett@kodak.UUCP
Message-ID: <1176@kodak.UUCP>
Source record: 117103

Is there any place accessible to me via uucp that keeps programs for the 8 bit Ataris online? I know of at least one BITNET site that runs something called Listserv. This site does keep 16 bit programs on line. All I have to do is send a mail message to Listserv at this site. In the body of the mail message I include the commands needed in order for Listserv to send back to me via return mail the various programs it has on file. I have never asked for any 16 bit programs since I don't own an ST. However, I have asked for and gotten files the Listserv knows of. Many BITNET sites run Listserv and each site keeps different sets of lists. Therefore, it would not be practical to send mail to each of them asking for the high level index of all their lists. So, does any one know of any BITNET site running Listserv that has an 8 bit archive? Are there any other sources of 8 bit software out there similiar to this?

Thanks for any help.

Well, actually, you can't just turn on one computer. If they are both hooked together, as soon as you turn one on, the other will start sucking power from it over the SIO cable. You can just plug one cable into the drive, boot that computer, unplug the cable, connect it to the other computer, boot it, and then plug in the first computer again. However, the real solution, thought of by Steve Ross, is to put diodes in the 5 volt line of the SIO cable. Steve said he'd actually done this, and it worked fine. This is probably the main function of the multi-atari to one disk drive/printer/whatever boxes.

1003. IBM hard drives to an MIO interface

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-16 01:41:02 UTC
From: rjung@castor.usc.edu
Message-ID: <497@nunki.usc.edu>
Source record: 117007

Hi, everybody.
A friend of mine here wants to hook up an IBM-type hard drive to
his MIO connector (which is consequently hooked up to his 130 XE). Problem
is, he doesn't know exactly what is needed for the task. The docs for the
MIO mention that you can hook up "SCSI-compatable" hard drives to the MIO;
Does this mean that the hard drive must come with an SCSI controller card?

Also, what special cables are needed to hook all this up (if any)? And
what DOS should he use to run all this? The manual recommends Spartados,
but could we use some other DOS (something that's more DOS 2.0 compatable,
maybe) while keeping the "free sectors" count accurate?

SOMEbody out here must have done this! Thanks in advance,

>
As a long time Atari 8bit owner, I watch the software scene pretty closely.
If an 8bit version of Sundog was ever developed, it was never released.
This is not too uncommon. Just last year Microprose announced that the
game Pirates was essencially done (this was at last years CES) and that
it would be released soon. Here it is almost a year later and still not
released. Maybe they figure they can never make enough money to make it
worth while but I find that hard to believe. It seems the actual programming
time is the single biggest investment.

My favorite rumor, though, is regarding Infocom's Bureaucracy. I really
want that game in the 8bit version and was delighted when it was actually
reviewed in an issue of Analog last summer/fall. Infocom sweares that
no such animal exists and that it is too large to make available for the
Atari 8bit. What a blow!

For "3 weeks" above, read "3 months." What I saw on Delphi (where ANALOG supports the Atari SIG) is that every subscriber will get the correct _number of issues_, plus an _extra 3 issues_ (monthly issues). I _think_ that this means that my sub. would be extended until August. As I recall, the label on my copy of the April issue says that my sub. runs out after July (last issue would be July), if I read (interpret) it correctly. Either way, I will be satisfied, since without any _extra_ issues my sub. would run out after May.

I remember (distinctly, because I thought about buying one) a gadget
that punches a "side 2 index hole" (or whatever you call it),
supposedly without damaging the disk. It was advertised in ANALOG (I
think, possibly in Compute! instead/as well) as a way to use the 2nd
side of double-sided disks (I recall that when I first started buying
floppies, the 2-sided ones were all that I could find in stores
anyway) with single-sided drives. It was called "Nibble Notch II,"
and was a variant of the "Nibble Notch" gadget that punches a "side 2
write-permit notch." (Both of these gadgets do _that_ I believe.) It
seems to me that this might be better than a notebook-paper punch for
the disks, even if it is not as wonderful as claimed (at least you get
the write- permit notch if your floppy doesn't have one - I'm talking
about _blank_ disks here, but the index hole is needed for write-
protected disks too of course).

To summarize, check your favorite Atari 8-bit mag's for ads for
"Nibble Notch II," it may be just what you (future) XF551 owners are
looking for (if this "problem" is real - sounds like it to me).

1007. Re: IBM hard drives to an MIO interface

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-16 19:51:02 UTC
From: gdtltr@vax1.acs.udel.EDU
Message-ID: <815@udccvax1.acs.udel.EDU>
Source record: 117011

I am a proud owner of the ICD MIO with 1 Meg of RAM. I do not have a Hard Drive hooked up, but I have looked into it a good bit. The MIO requires a SCSI controller between itself and the Drive. Some Drives (and Seagate with an N at the end of the name) have the interface imbedded in the drive. This is NOT necessary. External controllers such as the Adaptek 2070(A) will work just as well. It is just a matter of finding one. As for the cables, I think the docs for the MIO give a brief description of the requirements. In case you don't know, ICD sells most of the parts necessary to set up a SCSI drive, including controller, cables, case w/power supply and fan, the drive itself, and complete units. The advantage of this is that ICD supports its products. The MIO format utilities are designed primarily for the Adaptek, which is ICD's choice for the controller. By now, however, I'm sure that other formatters are available on their BBS. I called it once & got some neat stuff including a directory sorter, a new menu program, and a formatted directory lister. They also had SpartaDOS handlers for Happy drives, etc. If you have Sparta/MIO then it is a great place to visit. If you have a Hard Drive, it is a must.

A common cause for failure on Atari carts is comtaminated contacts. I had to actually replace the contact strip on the main board of my vintage '79 800. Frequently, I have had to take the cartridges apart, and clean the contacts with a residue free cleaner. Be careful with some types of erasers, they can leave residues.

******* FLAME ALERT *******

I hope what you were saying was a joke, if it was you can take this
followup in fun. If you really meant what you said be ready for some
heat.

I will take the issue's presented by this being, one a time
with a summary at the end.

In article <800@nuchat.UUCP> phillip@nuchat.UUCP (Phillip Keen) writes:
>
>I've been noticing talk about pirated software lately over the net. Well,
>I think it shouldn't exist, but it's something we've had for a very long time.
>Well, I know it's very easy to pirate software. With computers that can do
>multi-processing or multi-tasking it's very easy to do it because someone can
>load up something that is playing music and then load up a copy program and
>copy illegal programs. Anyways, what I think stores should do, is not let
>the lookers use the computers themselves, unless the store owners and salesmen
>know that person very very good. This would prevent much of the pirating that
>is going on right now.

You would expect people to go into a store and spent their money
on software without being able to try it themselves. The only reason I
use computer stores is the fact that I can try the software out, otherwise
I would use mail order. Most salepersons are not knowledgeable in all the
packages that the store carries and they are not going to provide you with
a sufficient demonstration. When I am making a purchase decision on software
weather it is a game or an application, I expect to be able to sit down and
use this software, to see if I like it. I want to get an idea how long it
take for commands to execute, how easy it is for me to use and to try some of
the features that I am particularly interested in. I would never buy from a
store that says, "You can't try it out, but I will show it to you". Maybe you
would spent $300 without being able to try out a peice of software, but I
most certainly would not.

> I also think they should have signs on their doors
>or something saying "We will take up your disks that you bring in here unless
>you've got a receipt from us with you." Therefore, people would hopefully
>not bring in their disks.

First, why are people bringing the disks into the store in the first
place, I don't think any store owner is stupid enough to not realize that
someone is sitting there copying the software. If a person is bringing
disks to the store, they probably are bringing them so they can test out
the compatability of their data on the new software, and where those disk

were purchased should have no bearing on the right to use them. I don't know where you shop for software, but people just don't open up the boxes and start using the machines, store have their own open copies which they let people use with supervision(not usually to stop them from stealing the software, but to make the sale, WHAT AN INTERESTING CONCEPT).

> About pirating over the modem. Well, that is a
>case that we the users don't have any control over, and if we did, because
>we don't know who's pirating everyone would have to take the consequences. I
>hope that it's something that won't keep us good guys (like me) who don't
>pirate out of BBSes if the government or anyone makes a law or a rule saying
>that we cannot use our modems.

We do have control over this area, if you are on a BBS and you see a copyrighted piece of software on it, call the publisher and inform them. If you think it might be by mistake, leave a note to the sysop and inform him that you think some programs on his system are there illegally. The way to combat this area of piracy is to report the crime when you see it. The software companies and the government are going after these pirate BBS's and will be grateful for your cooperation. I am the sysop of a Bulletin Board and I am very careful to check what is uploaded to my system is public domain, I also do not allow dicussion of piracy on my system.

> I think one way that we could get the pirating
>issue to go over is by not allowing anyone below age 35 buy a modem. The
>reason I say such a high age is I know some people between 20 and 35 that
>still pirate. See, most of the piraters out there are kids between the
>ages of 15 to 20. Anyways, thanks for the attention, and I just wanted to
>give my little soapbox on pirating. Phillip Keen

Okay moron, that's it, where do you get off saying that people under 35 pirate more than those over, if it is true, it is most likely due to the fact that more people under 35 use personal computers and you would probably find that the same percentage of users in each age group pirate. You claim that most of the pirates are between the ages of 15 and 20, while the number of people in this group who steal software is probably large, the value of what they steal is relatively low(mostly games that retail for around $40 and have no value after about a year). Where the middle age business person is taking home thousands of dollars worth of software from his workplace to use on his home machine, who is the bigger thief here. I know the retail value does not apply here, but the kid is committing a misdemenor when he steals Zork(n1), but Mr. Executive is a felon when he takes home a copy of 1-2-3(n2). They are both stealing, but all you ever hear small minded people like you talk about are those teenagers. I am 22 and I don't steal software (although I probably am capable of it), where would you classify me sir.
As for the feasiblilty of your idea, it is also absurd. Would you make it illegal for anyone under 35 to own a modem or just purchase one, would you make people register their modems like handguns(whach out BOB, I think he has a smartmodem ???). How would you keep people under 35 from using modems, DATA POLICE. It is just so ridiculus !!!!

Your foolish system would not allow students to have modem so they could access school computers or on-line data services. You would be resticting the rights of people under 35 to get the information that is available on these services.

As for your little soapbox, I hope you slip and fall off !!!

I think that I have said enough for now, I anticipate that others will also be nailing your small brian to a wall, so If I missed anything hold on.

(n1) Zork is a trademark of Infocom Inc.
(n2) 1-2-3 is a trademark if Lotus Development corp.

1) I've seen two identical messages saying that Kermit-65 was going to be re-posted. Is this going to happen or not? (If it is, and if the file is as large as someone in the last digest claims it is, maybe it should be broken up this time. No need to tie up the net.)

2) I don't have Lifespan, but I was under the impression that Antic put the documentation for their programs on the disk's flip side. Is this only true for some programs, or have the Lifespan owners out there somehow missed it?

They may not be STUPID, per se (although the general level of knowledge dis-
played in most computer stores {and there are a lot of them} that I've visited
over, oh, the last ten-fifteen years, doesn't really deny the possibility),
but most computer-store employees that I've ever seen are either ABSENT or
OVERWORKED when customers are in the store. I have RARELY if EVER seen a store
employee stand by a person who brings in their own disks, inserts them into
a computer on display, and does whatever he damn well pleases. In short, copy-
ing CAN and DOES go on in stores -- I've seen it.

> If a person is bringing
> disks to the store, they probably are bringing them so they can test out
> the compatability of their data on the new software, and where those disk

Maybe SOME of them, even MOST of them, are, but there is a definite non-zero
percentage of users who just walk in and copy stuff, and can get away with it
because the clerk or attendant or whatever is too uninformed (I still refuse
to say STUPID) to know what's going on. The original comment about "...unless
it is someone the store owners know very very well..." is RIDICULOUS -- half
the time, THOSE "very very well"-known people are the very ones doing the
copying, under the auspices (or at least the deliberately blind eye) of the
store owners, with whom they are in cahoots.

If you don't want a 60-plus-line lecture on my theory behind all this type
of thing, hit 'n' now.

If you haven't hit 'n' now, sit back for some theorizin'. I think this is
what it all boils down to. Comments/flames about content (to heck with SIZE,
yeah, I noticed it's big) welcome.

In the lifetime of any system, service, utility, etc., an "evolutionary process" occurs. A system (BBS, information service, Welfare, Social Security) starts out providing a good service, at an affordable price, to a small group of clients/customers/users, who enjoy a good bit of elbow room because the system has a LOT of RESOURCES, and FEW USERS. This lasts a while, but sooner or later the balance shifts. Users tell their friends how great the system is, the friends become new users, and soon there are MANY USERS and FEW RESOURCES. By simple mathematics, each individual user must now get a smaller piece of the pie. Resources themselves deteriorate, partly due to natural "wear and tear," and partly due to abuse from those users who, seeing a system with lots of extra capacity in the early days, don't worry about drawing conservatively on those resources for the sake of their lasting longer in the future. (Example: how long does a new city bus last before graffiti appears on seat backs, seat cushions are torn/slashed, etc., in addition to just plain loosening of bolts from road vibration? Or, how long can MCI or SPRINT keep up a particular LD access number and set of codes, before the "SmartModem" hackers break 'em and start using them for "free" phone service?) Managers gradually (or not so gradually) implement more and more measures (registration, licensing, proof-of-identity, security codes, secret passwords, etc. etc.) in an effort to counteract the abuses, but then the abusers just try harder, or work up new methods of abuse, and the process simply escalates. Of course, as a side effect, the service provided to legitimate users declines in quality, prices rise, and NOBODY's happy. The old-timers who were "there at the beginning" complain bitterly that "things were better in the old days," but nobody can really DO anything.

And so it is with pirating, whether by disk copy, modem transfer, or secret meeting in back alley. 'Way back when next to nobody had computers, there was probably (I wasn't there :-)) next to no piracy because there wasn't much TO pirate. Who'd take home a card deck of JCL statements, huh? But out in the wide world, human nature was what it's always been; as soon as there were computers and software, that segment of the population who tape LPs from their friends, rather than buying them, print fake IDs to get into bars a few years early, sneak onto buses, etc., extended their activities to copying/pirating software, and presto! - here we are today, with the Federal government feeling the need to intervene.

I personally am of the opinion that this is all "human nature," and therefore unavoidable. There doesn't seem to be any solution, even for the individual; does one wash one's hands of it, or try to fight it, or ignore it and fend for oneself in the cold cruel world? Whatever you do, you'll spend a lot of time angry, and there'll be a lot of people against you. On the other hand, there'll also be a lot of people who AGREE with you, and you can derive some comfort from sitting around b*tching to each other. Personally, I plan to do a little of all of these!

This should generate some interesting feedback; flame away!

If it can be done on an Apple II, it can be done on the Atari 8-bit (at least
on the XL/XE). The only reason for not porting Apple II or Commodore games to
the Atari is that there are (now) fewer Ataris.

I think you may be missing my point here, if the store employees are for the
most part absent, then they would not be around to enfore the policy of not
bringing disks. The proposed (although silly) policy would not work unless
carefully enforced, so in the stores you are speaking of they probably would
not even know if you brought in disks. So it really does not matter.

The deliberately blind eye is a completly different matter, we all probably know of stores that have more copies of XYZ than they ever bought and may even let friends copy, but the policies propoesed by the original poster will not affect this. This was the key part of my argument, all of his ideas were totally ineffective and would do more to hurt non-pirates than those who are stealing the software.

>early, sneak onto buses, etc., extended their activities to copying/pirating
>software, and presto! -here we are today, with the Federal government feeling
>the need to intervene.
>
The problem I see with a defeatist attitude like this is that if it becomes to prevalent, the federal government may be forced to step in and take action that non of will like. We must try to police ourselves somewhat so that we can aviod things like modem registration and federally issued ids for our hardware. The software publishing lobby is growing more powerful all the time. The major publishers can kill a new machine by saying that they will not publish for it. Excessive theft cuases the pubishers to rethink the plans for conversion of software and coming out with new packages. I agree than many companies charge to much for their products, but the answer is not to steal the product(Your use of it just increases its popularity), but to use another lower priced product. This will send a stronger message to the companies, when lower priced software sells well.

>I personally am of the opinion that this is all "human nature," and therefore
>unavoidable. There doesn't seem to be any solution, even for the individual;
>does one wash one's hands of it, or try to fight it, or ignore it and fend for

>also be a lot of people who AGREE with you, and you can derive some comfort
>from sitting around b*tching to each other. Personally, I plan to do a little
>of all of these!
While I agree the there will always be a portion of the market that will always steal the software, not matter what price it is. I feel that a reduction in price along with a better attitude by the publishers, could do a great deal to reduce piracy.

>
That would have the effect of killing most BBS's, if you start
registering systems, then you have to have a board to regulate them and
then there would be fees, waiting periods, lots of silly rules(like how
many lines your message screen can be etc.) With the pressure of
regulation, that would drive most of the part-time boards and many
others out of operation. I am a sysop, I don't allow anything to do
with piracy on my system, but If i had to go trough a pile of red tape
to keep it running I would probably shut it down.

This may be possible, but there would probably be a big fight to get the
law passed, since making copies of software for yourself would also have
to be made illegal by this process.(ie give these products no legitimate
purpose, then you could work to outlaw them). Also this would not stop
things, because underground copying programs would start to circulate.

This is clearly NOT true.

Actually, thanks at least in part to the XE Game System, the 8-bit line is doing quite nicely, thank you. We are in fact experiencing an upswing in interest, and therefore development, in the 8-bit machines.

I have trouble getting mail through to addresses like yours, so I didn't even try. I hope you read this. Looking through the latest issue of ANTIC, I see several sources that can be used. The ones listed below either listed them in their ad or are good sources:

MicrOtyme
PO Box 369
Kettering, OH 45409
1-800-255-5835
XE/XL Power Supply - $29

American Techna-Vision
15338 Inverness St.
San Leandro, CA 94579
1-800-551-9995 (orders only)
1-415-352-3787 (questions)
This is a good company for all kinds of parts

B&C ComputerVisions
3257 Kifer Rd.
Santa Clara, CA 95051
1-408-749-1003
Another good source for all kinds of Atari parts

Hope this helps.

| Well, actually,
| on an atari you have :
| sound 0
| sound 1
| sound 2
| sound 3
| And they can do A LOT with those voices. I think stereo is even
| possible.

It is possible and quite impressive. I have a PD program that plays one channel through the 800's speaker and the other channel through the TV speaker. This isn't multiplexed stereo, of course, and will not play correctly on the newer XL/XE line of 8bit computers because they do not have built-in speakers. I have seen plans that make adding a built-in speaker seem pretty easy, but I suspect a stand-alone separate box would be the easiest way to add a speaker.

Careful - that probably depends on what you mean by "support." I
have read in a recent article in ANALOG (4/88 issue, by Matt Ratcliff,
the 8-bit expert) that Atari seems to want to stop producing any more
NEW UPGRADES (i.e, machines with more RAM than the 130XE) for the 8-
bits. I have seen nothing (and I read the messages on Delphi
regularly, where the ANALOG magazine editors and even [occasionally]
Neil Harris of Atari Inc. hold forth) that indicates that Atari has
any plans to stop making or "supporting" the 8-bits. If you call the
lack of new h/w upgrades for the machines a lack of support, well,
that's another way of looking at it.

Combining two recent discussions here. How about connecting 2 XL/XEs
together through the joystick ports and having them play in stereo.
Either have a master/slave system where one computer sits around waiting
to make some sound; or a tandem system where one machine sends out a
'click' as it plays, and the other keeps up, playing music out of it's
own files.

Just pipe the sound through a stereo amp.
Hey, Imagine this with the AMY chip (dream on).

1032. C linkers

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-23 18:22:39 UTC
From: swklassen@trillium.waterloo.edu
Message-ID: <5945@watdragon.waterloo.edu>
Source record: 117036

I currently have the linker for the ACEC compiler. I am trying to improve my 6502 assembler so that it will output object code and label addresses in a manner that will let me directly link assembler routines with C routines. That is, I want to let the linker worry about the address of the assembler routine so that it does not need to be in a specific address. In order to accomplish this goal I need to know what kind of input the ACEC linker requires. If anyone has a copy of the source for the ACEC linker could they please e-mail me a copy. When I have completed my compiler I will be happy to post it to the net. (That would be in 4 or 8 months depending on how soon I will be getting my net access back [I lose it in a couple of weeks.].)

Thanks in advance to whoever may help.

Last year, in mod.risks, several reports about an individual in England being prosecuted for planting a "time-bomb" in a software system indicated the judge had ruled inadmissable a number of computer records because they had not been properly stored away. This implies that had the police there properly locked up the evidence (backup tapes in this instance) to insure against their being altered, that they would have been admissable as evidence...

Yes... To make a long story short, whatever is in Sector 1 of the disk is loaded into memory at hex 0700; the first 14 bytes or so contain information about how many subsequent sectors to load, where to place them in memory, and where to begin execution when said sectors have been loaded.

If no one else posts the fine points, I can dig them up for you and post to the net if there appears to be sufficient interest.

(This sure beats arguing about piracy, doesn't it!? :-))

I'm always up for a programming challenge, although my 6502 Assembly probably
isn't in the same league with many of you... If someone can send me the info
on the specific ARC format, i.e. the actual algorithms to be followed while
ARCing and unARCing a file, I'd be happy to muss around with it and post any
successes I may have, to the net... No guarantees, but I'd love to have the
ARC info to work with...

1041. ANALOG

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-26 06:23:33 UTC
From: daryl@ihlpe.ATT.COM
Message-ID: <2814@ihlpe.ATT.COM>
Source record: 117045

I received the letter I am sure every one else is. I was just about to
let the fiasco of the last several months slide when I read paragraph 3,
and I quote:

"In keeping with that goal [customer service] we have decided to extend your
subscription by three issues. That's right, you will
receive absolutely free three additional issues."

(And a free ginzu knife? :-)

Damn straight they better give me the issues I paid for. They decided -
DECIDED? - to extend my subscription? That was too
patronizing for me and was the last straw. And to top it off, my last ANALOG
was October, 1987. (Is that consistent with other of you out there?)
(NOV, DEC, JAN, FEB, MARCH - hummmm: thats five, not three.......)

The way you *should* learn is by reading the articles in
"news.announce.newusers", which exists expressly for the purpose
of allowing new net users to learn from everyone else's previous
mistakes, rather than by making the same mistakes personally.

I encourage everyone to (A) read all of news.announce.newusers at
least once per year, and (B) make a point of telling new net users
that it exists.

I'm even more tired of this message.
A simple way to kill this message (and other things cross posted to
several groups) is to put a properly worded line in your KILL files
(something like '/Newsgroups:*,*:/=:j' but this is a bit too heavy-handed)

This post exihibits an even more low-tech way, hopefully one that more
news software understands:-)

Good luck, all.

[minor flame]
Fortunately, I resisted the urge to reply to your original comments.

To anyone else who can't resist the temptation to broadly cross post inane comments and who maybe considering engaging in a similar learning scheme,

If you just want to "learn by trial & error", do it in MISC.TEST!!!!!!!

If you "just want to express your opinions", try TALK.MISC!!!!!!!

(Or rec.arts.frp, for you lightbulb jokesters. 8-)

[douse flame]

>Like I say I'm sorry.

Apology accepted. Lesson learned. Welcome to the net.

The structure of the boot sector is described in gory detail in "Inside Atari DOS" and I think also in "de re Atari". I don't have these references at hand right now but if you can't locate them I can try to tell you the salient points.

I think that you misunderstand what the letter is saying. You will receive
all the issues you paid for, PLUS three issues beyond that! This is exactly
what the ANALOG folks said on the DELPHI Atari SIG earlier this year; the
letter just confirmed it for me. The ANALOG folks (and their new bosses at
LFP Inc.) are not being patronizing, they are giving us something extra for
our trouble (a reward for our patience)!

Thanks for mentioning this! I've been a net user since about October of 1987, and this is the first mention I've seen of this newsgroup. I've had occasion to apologize for net-ignorance, due to having to learn everything by trial and error, myself, so I sympathize with all those now sitting there going "OOOOOOOooohhhhhh....!" Who's in charge around here, anyway? I want the full usenet manuals on my desk in TEN MINUTES... :-)

^^^^
Yep, that was the last issue I got before the current one.

It seems as though you have misunderstood ANALOG's letter. What they
meant was that you will recieve all of the issues that you have coming to you
plus three additional issues that you did not pay for.

So, if you had 4 issues left before ANALOG went on it's lengthy
vacation, you should get 7 issues before you will have to re-subscribe. So
you are getting 3 free issues. "That's right, you will receive absolutely
free three additional issues." Not just the end of your subscription
moved forward 3 months.

It's not that clear-cut in the letter Flynt publishing sent out, but I
have heard the information more clearly on the ANALOG-run Atari group on
Delphi a couple months ago.

1052. vt100 emulators

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-29 03:03:28 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8803290303.AA02847@mitre-bedford.ARPA>
Source record: 116906

Harlan Wolper asks:
> Does anyone know if there is any software available
> for the 8-bit Atari to emulate a VT100 type terminal?
> Or any other type of standard terminals for that
> matter? If so, where can these be obtained?

As long-term readers of these postings are well aware, there are several. The two most popular, so far as I know, are kermit65 and OmniCom. kermit65 is Public Domain, and includes not only true 80-column vt100 emulation but plain 40-column Atari emulation and an 80-column "scrolling" mode that displays only half of the 80-column screen at one time. This program does kermit file transfer but does not currently support key macro definitions or keypad emulation.

The other game in town is OmniCom, which is a "shareware" product, i.e., you are asked to send in $10 for an "official" disk and documentation if you decide to continue using the program after seeing what it does. I've been using OmniCom for over a year now and find it the best solution for my needs, because it DOES support keypad emulation and key macro definition, and because it has xmodem and plain ASCII capture and "Print Screen" functions, all of which I find extremely useful. With OmniCom, the only significant difference between logging in from my 800XL at home and the "real" vt103 at work is the 1200 baud line speed. And of course the ability to store and retrieve files and do local processing on the 800XL.

With either of these programs, you should use a monochrome monitor if at all possible, because 80-column emulation on an 8-bit Atari pushes the graphics resolution to the limit. Next best would be a composite monitor that has a separate chroma input, or an RGB monitor with an external NTSC decoder (or just drive the Green input with the Atari luminance signal). Finally, if you HAVE to, you can use some monochrome TV sets with acceptable results.

If you have the capability of downloading a file to your Atari, I can e-mail you a copy of either emulator in uuencoded form. If you need a disk, you might as well mail in your $10 to C. David Young, 421 Hanbee, Richardson TX 75080.

1053. boot disks

Newsgroup: comp.sys.atari.8bit
Date: 1988-03-29 03:41:48 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8803290341.AA03091@mitre-bedford.ARPA>
Source record: 116907

For Steven Klassen and anyone else who cares, here is a brief description of the boot process. When you power up with a disk drive attached and turned on, and with a disk in it, etc., the O/S will read the first sector of the disk into memory starting at address $0700 and then will look at what it got to determine how to proceed. The first few bytes of data loaded have the following meanings:

$0700 BFLAG Flag (normally 0)
$0701 BRCNT Boot Record Count (nr of consec sectors to read into memory for boot record (typically 3).
$0702 BLDADR Boot Load Address, i.e. where to put the stuff.
$0704 BIWTARR Initialization address
$0706 JMP XBCONT This is an actual jump instruction followed by a 2-byte address indicating where to go.
$0709 SABYTE Number of sector buffers to allocate
$070A DRVBYT Bit map of the disk drive unit numbers to plan for.
$070B Unused
$070C SASA Buffer Start Address
$070E DFSFLG DOS Flag
$070E DFLINK Sector at which DOS.SYS starts
$070F BLDISP Displacement in sector to sector link (differs for DD versus SD disk format).
$0712 DFLADR Address for loading DOS.SYS file.

This nomenclature assumes you will want to load DOS from the disk, as you would if your program planned to do disk I/O in the normal way, i.e. using DOS services. If not, some of the DOS-related names should still give you a clue as to what the loader will try to do with these locations.

First the O/S loads BRCNT consecutive sectors into memory starting with the first sector (sector 1) starting at BLDADR. Then it will do a JSR into the 7th byte into the area loaded, i.e. BLDADR+$6, or the JMP instruction at $0706 in the above listing. If what you are booting is a DOS disk, then the address XBCONT will lie in the block of sectors initially loaded and the code there will already be in place and will continue the load in whatever way strikes its fancy.

If you are booting your own thing without DOS, then evidently you need to start sector 1 with a 0 byte, then a byte containing the number of sectors you want loaded in the first gulp, then 2 bytes saying where to load these sectors, then 2 bytes saying where to JMP to initialize the program, and finally -- 6 bytes into the load area -- a JMP to the code you have provided to continue the load process. Everything after $0706 is apparently up to you. In particular, the initialization address called BIWTARR at $0704 will only get used if your code references it, I believe. By the way, if BRCNT is set

to zero it is interpreted as 256 sectors, so you can let the bootstrap loader load a whole program if it is anywhere up to 256 sectors long, so long as the sectors are contiguous. If it is longer or non-contiguous, you will have to provide code to read the sector links and figure out where to go for the next sector.

I hope this is enough to get you started. I also hope it is true. I am playing back what they say in "Inside Atari DOS", which pertains to DOS 2.0S. Your DOS may differ, depending on road conditions and your style of driving. I'm sure there are other readers of this august journal who can give you the benefit of their greater experience with how it all REALLY works.

I am new at this so please bear with me!
I have a Atari 800XL...how may I convert the Arc files listed above?
Also I have a 850 and I tried to connect to a Star LV 1215 printer
When I send data to it it sends it..(ie says 'Ready')....but the data
gets 'LOST' it never gets to the printer.
I tested all my equ. out it isn't a hardware problem.
I asume it is an interfacing problem.

(pin-outs as follows)
```
================================================================================
850 printer(centronics)
--------------------------------------------------------
1 strobe 1 strobe
2 data0 2 data1
.....
.....
8 data6 8 data7
15 data7 9 data8
13 busy 11 busy -----goes lo when ready
12 fault 13 select -----must be hi to print
11 sig gnd 16 sig gnd
================================================================================
```
If anyone can help it would be a massive favor as this printer is currently
sitting in my room collecting dust!!!

^^^^^^^^^^^^^^^^^^^

John, you're mistaken. Kermit65 DOES support a VERY GOOD keypad emulation.
The mapping of functions to keycaps (all SHIFT-CONTROL combinations) is quite
logical and consistent, and I am able to use it just as fast as a "real" VT100-
and I'm a FAST typist.

> The other game in town is OmniCom, which is a "shareware" product...

[more verbiage deleted for vnews' sake]

> I've been using OmniCom for over a year now and find it the best solution
> for my needs, because it DOES support keypad emulation and key macro
> definition, and because it has xmodem and plain ASCII capture and "Print

I second the motion that having all the different file-transfer protocols in
one program is a great thing! It's quite a pain to log onto a BBS or whatever
with Kermit (my fave 'terminal emulator') and then have to switch to 850 Ex-
press! to perform an XMODEM transfer!

However, I found that OmniCom's PRINT SCREEN function (an option that can be
turned ON or OFF to "print all incoming data," as I distinctly remember it)
was unsatisfactory, because it wasn't able to do anything effective with the
escape sequences typically sent to a VT100 for screen and cursor control.
Even "stripping out" the escape sequences would be better than PRINTING them,
but not even THAT is done. I found it completely impossible to print a data-
base form-entry screen, once screen-painting was completed. Did I miss a
feature that lets you print an image of an EXISTING DISPLAY?

[more deletions for the sake of the line counter]

I've gotten readable 80-column results on a standard color TV; you have to
turn the contrast way DOWN, and the brightness way UP, though.

[John Sangster's closing comments deleted; sorry John, the line-counter
made me do it!]

Does anyone around here have a copy of Inside Atari DOS, or know where to get one? I've been having a heck of a time trying to find it, since last seeing it and (in retrospect, stupidly) NOT buying it, back around 1983 or 4. Rumor has it that it's out of print, but does anyone know for sure? If all else fails, I'd love to have the hotline (800 number or otherwise) to COMPUTE! themselves, so I could get the scoop "straight from the horse's mouth."

E-mail or post here. Thanks.

Due to this and other requests received through E-mail, I am in the process of composing a description of the boot process, necessary disk format, and so on, which I will try to get posted to this newsgroup within the next few days. I'm taking the info presented in the Atari OS User's Manual and rendering it into comprehensible terms. I don't know 'bout YOU, but I've always felt that there were lots of huge gaps in the docs for this machine, and what's there often isn't very clear! I'm trying to avoid that in my summary, so please bear with me.

I think you have the Capture and Print-screen features mixed up. Print screen
(I forget the key combination! I think it's [SELECT][OPTION]) dumps, to the
P: device, whatever is on the screen. Capture mode puts a copy of all
incoming characters (or at least most of them) to a user-specified device.
Print screen works fine for me, but not Capture. I think I'm on to a BIG clue,
though - when I tried capture to a D: file instead of to P:, many of the
characters were inverse video when I looked at the file. Hmm, 8th bit flipping
around, eh? Parity? I have to make parity=none to get xmodem (binary files)
to work, so I wonder what's going on.

1070. Re: Booting up without AUTORUN.SYS

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-01 09:16:28 UTC
From: flex@cup.portal.com
Message-ID: <4254@cup.portal.com>
Source record: 116924

Hmmm, didn't know that there were any Atari 8-biters left out there...!

Anyways, concerning creating Boot Load Disk programs. The best place for a technical reference is The Atari Technical Reference Notes -- a collection of usage notes written by the creators of the Operating System themselves. This pre-dates the acclaimed De Re Atari and of course OSS's Inside Atari DOS. In fact these reference notes were internal Atari Corp documents, later released to the public.

Oh well, here's the "Great Secret". Heh.

The normal Atari disk format (single density) consists of 720 sectors, of which only 719 is used by DOS (a boo-boo, but dats another story!). When the Atari is Cold-Booted connected to a disk, the OS will attempt (among other things) to "boot" from the disk drive. The OS will read in Disk Sector #1 into its Cassette Buffer at $0400 (yea crazy, but so what.)

Of this 128 byte record, only the first SIX bytes have any initial signi-ficance:

BYTE #1 Boot Flag Thrown away by the OS due to meaness, stored at DFLAGS $0240 for fun while its at it.

BYTE #2 Rec to read The number of sequential disk sectors (records) to read in after this initial read. DBSECT $0241

BYTE #3,4 Load Address Where to move this boot sector (#1) in memory following the Lo,Hi 6502 word address format.
Saved in BOOTAD $0242.

BYTE #5,6 Init Address The Initialization Address (Lo,Hi) for this prog.
Saved in DOSINI $C

So after the Atari looks at these first SIX bytes of Disk BOOT Sector (#1) then it goes like how you expect. This first record (#1) is moved to the address specified by BOOTAD. Then the OS will read in sequentially (like Disk Sector #2 and on...) the number of sectors (also called records) as specified by DBSECT. As one can figure out, DBSECT is decremented internally by one till a BEQ state exists. So an initial value of ZERO for DBSECT allows 256 sectors to be read in. Remember this is jus a boot load, and a small program can be read in to read in additional disk sectors in any order, to any address. This is called a multi-boot process.

As a side note, you may be a wonderin how in the world one can write a program to read in additional disk sectors after the inital boot process, without DOS present?

Well, how da ya think the OS can read in the boot sector in the first place...? Yup, there is a Resident Disk Handler in the OS that is a low-level access of a disk (lower than CIO... actually called SIO for Serial Input/Output, but dats still another story).

So dats about it. The OS reads in the required amount of sectors and stores it anywhere in memory, as specified by BOOTAD. When Atari DOS 2.0 gets booted in, the BOOTAD is set at $700. But as you have seen, it can be anywhere in memory a programmer chooses.

Oh yea. After the initial boot disk load ends, what happens? Well, FIRST the OS will AUTOMATICALLY jsr to BOOTAD+6. This "feature" to befuddle the masses is called a multi-stage boot. Jus do a CLC/RTS combo to get it outta here correctly. After this, the OS will then jsr to DOSIN.
And dat is where your boot loaded program should be!

Opps, in the jsr to DOSIN coding, a RTS will push the OS to JMP to DOSVEC ($A), so ya better set DOSVEC in ya code to an address. However, a RTS in your DOSIN coding ain't necessary.

If anyone has anymore questions about this, or about Atari 8-bits in general, jus leave a note!

1071. Microsoft Basic

> I can log off of our IBM mainframe.... Any help would be appreciated...

May I remind users of OmniCom that it is a shareware product, and that excellent documentation comes on the disk version, which you are supposed to order for $10 from David Young, 421 Hanbee, Richardson TX 78050 (?check ZIP code) if you plan to use it on a continuing basis.

However, I can see how John Bunch and others might like to verify a few details like the above to ensure useability of the product before paying even the minimal $10 fee, so I will include the following hint: The OPTIONS key selects the menu, and I think it is P for Parameters on the menu across the top which will let you walk through most any tailoring your heart could desire. In particular, you can program the sequence sent by any valid key combination, e.g. normal key, SHIFT+key, CTRL+key, or CTRL+SHIF+key. For a few keys, CTRL or CTRL+SHIFT doesn't work or doesn't really give you a new key, but otherwise you can make any key send any string of bytes you like.

So it's just a matter of mapping the valid combinations into what you need. For example, ` is Hex $60, so you type whatever key (or CTRL/SHIFT combination) you want to have send `, then you can enter the Hex code directly as 60 and a <RETURN>. Then a <RETURN> by itself and OmniCom will ask you if you want to save these parameter values, which you presumably do.
Here is a suggested mapping: Map the "Atari" key into Line Feed because it is in the same location as LF on a vt100. Map SHIFT+<atari key> into tilde and maybe CTRL+<atari key> into your ` character, if in fact SHIFT and CTRL give differently programmable keys. Incidentally, I also mapped CTRL+<numeral> and CTRL+SHIFT+<numeral> into Hayes modem autodial sequences, i.e. ATDT16175551212 type things, giving a total of twenty custom autodial codes!

I don't know offhand if any key sends ` without your programming it, but you'd probably find it more convenient to choose a key like the Atari key to do it anyway.

According to the Atari Operating System User's Manual, these six bytes are
ALL you need concern yourself with for a pure autoboot disk; the remaining
bytes are specific to the DOS 2.0 boot process, which the OS User's Manual
cites specifically as a "special case of diskette-booted software."

> $0709 SABYTE Number of sector buffers to allocate
> $070A DRVBYT Bit map of the disk drive unit numbers to plan for.
> $070B Unused
> $070C SASA Buffer Start Address
> $070E DFSFLG DOS Flag

> $070F BLDISP Displacement in sector to sector link (differs for
> DD versus SD disk format).
> $0712 DFLADR Address for loading DOS.SYS file.
>
[interpretation of byte functions omitted]

This set of locations are DOS-related ONLY, and aren't significant to the
boot process itself. They can, and often do, contain executable code.
The special functions above are valid only when the program to be booted is
the DOS.SYS portion of DOS 2.0.

[process description omitted]

> (you can autoboot a program...) up to 256 sectors long, so long as the
> sectors are contiguous. If it is longer or non-contiguous, you will have to
> provide code to read the sector links and figure out where to go for the next
> sector.

This is important to remember, because the boot process doesn't use the concept of "files" on the disk; unless you load in your own file management software, too, you won't be ABLE to access the disk as files -- no directory, no VTOC, will exist except as managed by YOUR program. The built-in disk handler in the computer operates ONLY at the SECTOR level.

>
> I hope this is enough to get you started. I also hope it is true. I am

> Your DOS may differ, depending on road conditions and your style of driving.
> I'm sure there are other readers of this august journal who can give you
> the benefit of their greater experience with how it all REALLY works.

As far as I can tell, John got it right. In fact, his posting is so concise that it obviates any need for me to duplicate his effort by posting my own long-winded version. On the other hand, I remember being EXTREMELY confused and uninformed by manuals explaining things by saying "load stuff starting at LDADR and then jump through DOSINI" or whatever; if there's anyone reading this who doesn't follow the notation, make sure you speak up. I hated that more than anything, but had to bull through it without benefit of the net; as a result, progress has been slow... you have a chance to do better, so take advantage!

Aha! At last an easy question!

> DOES ANYONE KNOW OFF OR HAVE A PROGRAM
> THAT SIMULATES A METRONOME USED
> TO KEEP TIME FOR MUSIC.

Try this little BASIC program for this purpose:

```
100 ? "BEATS PER SECOND";:INPUT B
105 ? "TOCK SOUND";:INPUT TP
110 T=400/B:REM USE 447 FOR OMNIVIEW
120 SOUND 0,TP,10,15:SOUND 0,TP,10,11:SOUND 0,TP,10,7:SOUND 0,TP,10,3
130 SOUND 0,0,0,0
140 FOR I=1 TO T:NEXT I:GOTO 120
```

You can try different values of TP for the "Tock Sound". This controls
the tone pitch that is used in the metronome sound. A value of about
40 seems good to me, giving a kind of "woody" sound, while small values
around 3 or 4 seem more "metallic" to me. If you pick a sound you like
best you can replace line 105 with a statement that just sets
that value, e.g. TP=40.

Enjoy!

Source record: 116931

There are a number of programs available to do this, but I don't know if
they're in the public domain. Most of them seem to be sold in packages with
disk editors and other such potential protection-busting tools.
If no-one else replies, I'll try to look up a few. I don't own one right now,
but I'm considering buying one.

Does anyone out there on the net have one short enough to post?

Jim Shaffer, Jr.
ShafferJ%Bknlvms.Bitnet@cunyvm.cuny.edu

P.S.: It's important to know if you're dealing with a standard cart or a
bank-switched "super cart." I don't imagine that there's an easy way,
and therefore any way at all, to produce an executable disk file from
a bank-switched cart. The problem would be not in extracting the code,
but in hacking it into a form which would run as a continuous program
rather than trying to bank-switch a non-existant copy of itself :-)
If I'm wrong, let me know.

1079. R: emulators for atari modems

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-04 16:51:34 UTC
From: tpcharron@dahlia.waterloo.edu
Message-ID: <6203@watdragon.waterloo.edu>
Source record: 116933

This is a request to the net for information. I currently have an atari xm301 modem, and would like to have 80-column emulation. The only possibilities that I've found so far are by using either KERMIT65 or OMNICOM. The problem is that both of these emulators use the R: handler, and the atari modems have a T: handler. I need some sort of R: emulator for my system.

I've heard of a program called SMARTT which may work. If anyone has info on it or any other alternative (software) solutions, I'd appreciate them.

Thanks.
Tim Charron

1080. Boot sector

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-05 12:47:00 UTC
From: AXDFM@ACAD2A.BITNET
Message-ID: <8804051710.AA21410@ucbvax.Berkeley.EDU>
Source record: 116934

For those of you interested in creating boot disks:

You may create the boot sector just fine, but you must put the file on the disk correctly too. My bet is that you ARE using some kind of DOS for your program development. If that is true (which it is), then the program itself will saved in individual files, right? You have to get the program into a "pure" sector format manually. Here is what I mean:

At the end of each sector, Atari DOS 2.x places three bytes for dos usuage. These bytes contain the file number and (most importantly) the link to the next sector. If you are creating a boot disk, and just try to modify the boot sector to force load an 2.0 program, then you will run into problems. SIO doesn't know about these extra three bytes, and will read them in as program data and not DOS information. You are going to have to write the program itself to the disk in a pure format, eg = without the three trailing bytes. Omnimon is the easiest way to do this, but not always feasible. The best way is to write a small BASIC program that will do the job quick and dirty. (You will need less than a screen of code for the BASIC program.)

Creating a boot disk involves knowing more than just reading w/o a DOS, but includes writing the information in the first place. This is not a difficult thing to do, but it does require a thorough knowledge of what you are wanting to do.

Note: For those who are intimate with SpartaDOS on a very low level might want to look through their manual. Sparta doesn't put a 3 byte trailer on each sector, but uses seperate sectors to form a file sector map with the program taking up complete sectors (eg= no trailers). An enterprising programmer could use this information to create a boot disk on a sector level, but why not just use Sparta's BOOT command for this? Read your manual for details....

Any further help I can be in actually getting the information on the disk into the first place, please holler at me....

1081. ARC

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-05 12:49:00 UTC
From: AXDFM@ACAD2A.BITNET
Message-ID: <8804051707.AA21374@ucbvax.Berkeley.EDU>
Source record: 116935

There is an in-depth article in the latest Computer Shopper concerning ARC compression techniques. Those of you interested in writing a new version of ARC will find it most useful in doing so. Very complete information is there, so I am sure you won't be disappointed....

Source record: 116937

If it's the same thing I've seen, it's far from new.
It's basically (argh....) a BASIC with commands and functions somewhat
more "standard" (whatever that means) than Atari Basic.
Notably, it has standard string functions, e.g., LEFT$, MID$, RIGHT$, etc.,
and string arrays.
As for graphics and sound, I couldn't tell you. I never bought it.

From: rjung@castor.usc.edu
Message-ID: <648@nunki.usc.edu>
Source record: 116938

In article <8803290303.AA02847@mitre-bedford.ARPA> jhs@MITRE-BEDFORD.ARPA writes:
> [Lots of stuff about VT-100 emulators deleted]
>
>With either of these programs, you should use a monochrome monitor if at all
>possible, because 80-column emulation on an 8-bit Atari pushes the graphics
>resolution to the limit. Next best would be a composite monitor that has a
>separate chroma input, or an RGB monitor with an external NTSC decoder
>(or just drive the Green input with the Atari luminance signal).

Please forgive me if this question sounds stupid or ridiculous (I don't
know *anything* about hardware), but do you know where I can buy a
commercial NTSC decoder for my 8-bit Atari?

If nothing else, how about detailed instructions for making one?

Any information will be appreciated,

I'm looking for opinions about which mail order places for 8-bit stuff are good, and which should be avoided. I'm mostly interested in promptness of delivery and non-screwups, but all data are welcome. I'll summarize to the net if anyone's interested. Thanks in advance.

1086. Re: Microsoft Basic

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-06 12:23:35 UTC
From: usenet@shell.com
Message-ID: <230@shell.shell.com>
Source record: 116940

Yes, it is a very powerful implementation. I would recommend using it only
for limited idea testing, though. Seems like you get about 20k from after
loading the extensions and that might make things a little tight. As far
as compatibility with other versions of MSB (my experience is with CP/M
MSB), not too much has to be changed. Maybe the OPEN statments. And
a few other stuff (CP/M MSB does not have the atari graphics commands.)

I used mine in grad school for calculations in E&M, and quantum. When I
had the idea fully thought out, I'd translate the program to FORTRAN and
run it on the university mainframe.
From: svh@shell.com (Steve V. Hovater)
Path: shell!svh

One thing you might notice, is that the syntax checking you may be accustomed to
in regular Atari Basic is not present in MSB 2 - it's done at runtime.
Which may or may not be to everyone's liking.

Disclaimer: These opinions are ordinarily my own, and couldn't possibly
reflect the views or opinions of my employer.

1087. Re: vt103 emulation standards suggested for the 8-bitters...

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-06 19:12:17 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8804061912.AA04304@mitre-bedford.ARPA>
Source record: 116941

Aha, there really ARE keypad functions! I guess I didn't get that far through the manual, because I have been telling people there was no keypad emulation. Sorry about that. I tend to get impatient with reading long manuals, and it is certainly unfair to your yeoman efforts on kermit65 that I have misinformed a number of people. I'll have to print a retraction.

However, I would like to lobby for a more user-friendly implementation than that described in the Version 3.3 kermit65 documentation.
I use a real vt100 at work and OmniCom at home, and I would go bonkers (for awhile, at least) to have to map from needed function to printed symbol on a vt100 (which, recall, I would not have at hand when needing the information, since I would be at an Atari terminal, not my trusty vt100 at work), to corresponding printed symbol on the Atari, which is usually but not always the same, to new location of said symbol on the Atari keyboard.

What is so nice about the OmniCom implementation is that just about everything is mapped isomorphically in a geometric sense -- the keypad layout is a 4-by-4 pad made up of

```
1 2 3 4
q w e r
a s d f
z x c v b n (v=ENTER, b=0 and n=.)
```

with only the b and n being out of place. They are the "last row".
When I started using OmniCom, I had been a user of "vt10sq", which uses the same geometric layout, but requires you to type "ESC" before each keypad key to indicate keypad mode. David Young kept the layout, which made my life easier, since I had by then gotten very used to mapping between it and the real vt100. I suggest that these two precedents -- vt10sq and OmniCom -- are popular enough that if there is to be a standard location for the keypad on the Atari keyboard, this is probably the right place for it. For one thing, the 1 2 3 4 is easily mapped to PF1 through PF4.

David then enhanced the keypad operation by going to the convention that pressing the SELECT key and holding it down turned on keypad mode for those keys. This was a very great improvement over the vt10sq convention of prefixing each keystroke with "ESC", but was slightly clumsy for me as a right-hander, but I have gotten used to it. Lefties should love it. I later suggested that he read the joystick trigger button too, so right-handers could use it, and place the joystick over at the left side of the keyboard, leaving their right hand free to peck on keypad keys.

The cursor keys can be mapped right onto the Atari cursor keys, delete/backspace to BACKSPACE, CTRL-delete/backspace to DELETE

(I think that's how I did it -- my several hosts and application
programs are a bit schizoid on this point). Also, I like using
the Atari / reverse video key to map into Line Feed, and SHIFT/Atari
to map into Tilde, which one needs a lot with unix. The Atari key
on the 800XL anyway is RIGHT where the LF key on a vt100 is, making
it a natural reflex to poke it when what you want is "ARG" in the
Rand editor, or a real LF. But all this is straight macro definition.

I think this point of view, that users may well switch back and forth
between the real terminal and the emulator and that a graphic or geometric
emulation of the keyboard will be most helpful, should be used to guide
your final keypad emulation and key macro definition facilities. Of course
key macro definitions per se are pretty flexible anyway. In fact, if you did
nothing more than add macro definition capability, and used SELECT to define
the whole keyboard as a new character set, then of course one could define the
keypad anyway he/she wanted to. The only penalty would be duplicated storage
of a lot of ESC sequences (what, maybe 30 or 40 bytes?) and of course extra
effort to program the keypad macros versus inserting the constant part
automatically.

(Speaking of definitions, they ought to define "se" in English to mean he/she.
Hah, I hereby do so. Spread the word.)

OMNIVIEW (and I think standalone OmniCom too?) uses the HELP key to toggle
screen scrolling on and off. This is a lot easier to do than CTRL-1, as
supported by the Atari O/S, but of course it pre-empts the HELP key.
Then again, I haven't seen any program that uses it other than OMNIVIEW.
Then again, that reasoning is not my idea of good software engineering
practice. If flow control is implemented, one could of course use CTRL-s
and CTRL-q fairly conveniently.

I hope other comments from the Net will be stimulated by the above. Now
is the time to influence the final form of kermit65.

1089. Compute! Books / De Re Atari

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-06 23:03:00 UTC
From: PARSONS@KSUVM.BITNET
Message-ID: <8804071312.AA28561@ucbvax.Berkeley.EDU>
Source record: 116943

Here is some information concerning the aquisition of any Compute! book
and De Re Atari.

To order any Compute! Book or check the availablity thereof:

Call: 1-800-346-6767 Write: Compute! Books
Customer Service
(As published in Apr 88 issue.) PO Box 5038
FDR Station
New York, NY 10150

For De Re Atari:

Call: San Jose Computer Cost is approx $13.00
1-408-224-8575

As of February, when I ordered my copy, they had "a few left."

Before purchasing De Re Atari, I'd like you to consider what it offers.

The book comes unbound so you will need to buy a 1 1/2 inch notebook to
keep it organized. It has sections covering the Antic chip and what it
does/how to use it, DLI's, PM graphics, Scrolling, Sound, the OS, DOS,
and an Atari BASIC overview. It also has appendices that cover memory
utilization (how to use memory efficiently in programming, NOT how the
computer uses the memory), user friendly programming, a cassette drive
overview, artifacting, and the GTIA.

For the last week or so some people have been interested in making boot
disks. For those people, I will summarize what De Re Atari has to
say about DOS.

De Re on DOS 2.x: * explains (somewhat) the Resident Disk Handler
and the File Management System (FMS)
* overviews DOS commands
* talks about RND Access files (how to make them)
* Gives simple Diagram on disk format
(what is where--ie sector 1 boot sector,
sectors 2-81 DOS.SYS....)
* explains Volume Table of Contents (VTOC) layout
(VTOC tells how much of the disk is used)
* explains Disk Directory format
(simple diagram included)
* explains individual sector format
(simple diagram included)
* briefly mentions the boot sector
* explains AUTORUN.SYS files and how to make

them

For those interested in an indepth explaination, I would suggest purchasing Inside Atari DOS. For an overview an short explainations on DOS--De Re Atari. De Re tells somethings, but not quite enough (as with all Atari related documents).

By far the most usefull section of De Re is the section on scrolling. Chris Crawford wrote that section (along with 3 other sections), and explains scrolling fairly indepth (better than any other publication). For those interested in graphics this section is a help.

All in all, De Re is a worth while purchase. Heck, its only $13.

I hope I have assisted many Atari people in their purchasing decisions.

1090. AdvanBasic

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-07 09:18:40 UTC
From: shafferj@bknlvms.BITNET
Message-ID: <8804052209.AA25737@ucbvax.Berkeley.EDU>
Source record: 116944

Does *anyone* on this list use Advan Basic? I've never met anyone else who does, and it's pretty frustrating. It's a great product (my only major gripes are the price and the fact that it can be slower than one expects from a compiled language, but the available commands and functions are excellent). Unfortunately, Action! seems to be the language of choice. I don't know whether that's because it came out first, or if the vast majority of Atarians learned C or Pascal as their first language (although Action! is really neither), or just what the situation really is.

If there are any users here, have any of you written any useful programs, functions, or subroutines that you'd like to share?

Can anyone tell me if there's any Advan software on CompuServe? I haven't seen any, but it's been a while since I checked.

Thanks in advance,
Jim "Headroom" Shaffer, Jr.

I figure that this probably could be done, but thereis one problem: speed.
Before anyone freaks out on me, I know that swapping speed is no problem, but
to effectively run a 3D system you have to have the computer compute a 3D
image from two perspectives. It could be that the 6502 just can handle
that sort of thing in a reasonable amount of time. Sure, it would be no
pproblem to make a neat picture and show it in 3D, but for it to be worth the
money you would have to put into it, it should be able to do more.

.violation if the owner cannot produce an "offical" copy.
.Arthur L. Rubin
.
Computer based records can be entered, as long as certain ground rules
are observed. They can be entered to prove that the information they
contain is actually true, if they fall within an exception to the
hearsay rule. For example, business records kept in the normal course
of business, when introduced and authenticated by a custodian, can be
so used.

They may also be used against a party to refute something they said,
or to show merely that they have an illegal copy, etc. In any case,
all records must be properly authenticated, but this is not much more
difficult than for other kinds of documents. For example, here in
Dallas, two engineers were convicted of theft of trade secrets when
tapes full of software taken from their previous employer were found
at their new employer, and it was shown that the software had been
loaded onto the new employer's system.

There are no typos. If you think you saw one, see an opthamolo... optaha...
ophthamal... eye doctor.

1093. 3D on the 8-bits (was Re: Advan Basic)

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-07 16:51:29 UTC
From: rjung@castor.usc.edu
Message-ID: <666@nunki.usc.edu>
Source record: 116947

It was speculated on the net of whether or not 3-D glasses can be used on the Atari 8-bit, ala "Stereotek" for the ST's is being done from Antic.

Just to throw in my (ignorant) 2 cents here: I don't see why not.
In theory, all you need is a pair of LCD glasses that can switch the lens transparency from left to right to left to right every 1/60th of a second, and have that synchronized with two alternating images shown on the screen.

From a software point of view, you're probably talking about page-flipping the pointers to screen RAM every 1/60th of a second, and sending a signal to the glasses (via the joystick port?) to "switch" the glasses around accordingly...

Of course, there's probably a very good technical reason why this can't be done (Maybe a screen-refresh VBI can't do this much work?), and I really don't know what I'm talking about (much less how to actually WRITE such code B-), but it's too early for me to think coherently anyway...

--R.J.
B-)

P.S. The only other place where this glasses technology is being used is on the Sega game system, which works exactly the same as the Stereotek glasses...But then again, the Sega uses a 68000.

P.P.S. If anyone's wondering, the upcoming "3D" episode of Moonlighting (May?) will *not* use anything this elaborate...

Help! I have talked with JRD@STONY-BROOK.SCRC.SYMBOLICS.COM (the author) extensively, and this is my last hope. For some reason, I cannot get a working copy of Kermit65 from the VAX I'm working on, to my Atari. Here's what I do: DL Kermit65 (ver. 3.3) w/ ver. 3.1, using Atascii translation; run the BASIC UUE decoder program -- decoded output is 24622 bytes and encoded data (direct from VAX) is 33939 bytes; I then try to load the new versin of Kermit65. I hear the 850 handler initializing and then....nothing... total lockup...well, not total...I can get out via Reset. I am using a 320K XE and SpartaDOS 3.2d. Any and all help is appreciated (including a long-distance number from which I might directly DL the object code for the newest version).

Thanks,
Mike

>the pointers to screen RAM every 1/60th of a second, and sending a signal to
>the glasses (via the joystick port?) to "switch" the glasses around
>accordingly...

You don't even need to do that. At the end of a display list, there is a
wait-for-vertical-blank-then-jump instruction, with the jump addr normally
being the beginning of the display list.

This allows the graphics chip to do the alternating. You would have two
display lists, one for each of the images,
but instead of the jump at the end of each one being back to its
top, have it point to the top of the other display list. A DLI at the very
end of each display list could be used to flip the LCD glasses.

I have used this technique to get more gray levels, but the image seems a
little flickery.

Does anyone has any information about the R: Verter ??? I think it

was a cable with a handler to allow the connection of a modem without

an interface. I would also like to hear some comments new atari modem.

Does it come with a handler to use with any 8-bit terminal program or

can you only use certain terminal program???

Any comments or suggestions would be appreciated.

I wrote a program that ticks like a metronome according to
what speed you set it to. I think it also takes musical terms
(like presto) and equates that to roughly equivalent speed (I haven't
looked at the program for years).

Source record: 116953

Scott Parrish's suggestion of a 1.5inch ring binder for "de re Atari" reminded me that I found that you can get such a document bound in a "GBC" binder (General Binding Corp., Chicago) -- the kind with the plastic spine with fingers and rectangular holes in the pages -- at many local print shops for around $1.50. Check it out -- it's about as easy to use as a 3-ring binder, probably cheaper, and certainly more compact. Hint: A transparent vinyl front cover and a black vinyl back cover looks very professional if the cover page of the document is atractive, which is certainly the case with de re Atari.

Another hint: I like to include 5 to 10 blank pages at the back for handwritten notes when I send it in to be bound.

Still another: If you work for a sizeable company with their own print shop, they almost certainly have a GBC binder machine they'll let you use if you sweet-talk the right person.

Question: Are these guys duplicating it themselves? Is this a legal source?

As Robert Jung (rjung@castor.usc.edu) said, there should be little trouble for the software. A few pokes for the display list and a poke to the PIA chip.
Of course, any program you were running would be a tad slow considering the extra work you would need to display 3D (even fake 3D like in 3D comics). I think the big hurdle would be the glasses and the attendant hardware.
How much would the circuitry cost, and where would you get it from? Would you rip up a Sega 3D thingie?

Re: Mail Order for 8-bit software

I like Software Discounters of America. At one time they didn't carry any software with the Atari brand name and they're not advertising Atari brand titles in their latest magazine ads but they have lots of other software and some hardware as well. I usually get all excited about my Atari 800 every December and order a bunch of games for Christmas. I've never had any problems with SDA. Order line: 1-800-225-7638, free shipping over $100, no surcharge for VISA/MasterCard.

Another fun place is B&C ComputerVisions. They carry closeouts, weird hardware, and lots of Atari memories (not RAM, history). Their prices on normal software are not all that great. I haven't actually ordered mail order although I know someone who has. Instead, I showed up in person and had a great time looking over all the 8-bit stuff and got several games and some reconditioned Atari joy sticks (and avoided the temptation to buy the Newell Floating Point ROMS for my 800). This place is a must-see for Atari nerds on business trips to Santa Clara, CA.

Source record: 116956

Ok, let's talk about games. I have lots of games and I want more. And some of those new XE games look pretty good. But I have a 48K 800. Will they work, he wonders?

I wish Atari would say but they only mention XE and XL systems on the boxes.

Here's what I've heard:

Rumor 1: "None of the blue box games will play on old Ataris." -- Kaybee Toys salesperson.

Rumor 2: "Everyone we've tried has worked except for 'One on One'". -- B&C ComputerVision salesperson.

Here's what I know:

XE Cartridge 800/48K 400/16K

BattleZone Yes No
Rescue on Fractalus! Yes No
Flight Simulator II No No

Anyone know or care?

I have seen the sources for the Atari ST version of ARC available on Atari's
own BBS system. It is however a LONG download, about a 350K file. The IBM
version is around the same length.

I don't have my Atari next to me here so I can't say for sure, but wouldn't
the OS/VBI shadowing of DLISTL $D402 (?) from SDLIST $230 interfere? I believe
you have to 'turn off' shadowing before you can really use the wait-VBI-jmp
instruction.
In any case the project from the software point of view is pretty trivial
we all agree on that.

P.A.C.E. (Pittsburgh Area Computer Enthusiasts) presents the Second Annual Tri-State Atari Computer Products Show at the Expo Mart, Business Route 22, Monroeville, PA. The show will run from 10:00 A.M. to 5:00 P.M. on Saturday, April 23, and from noon to 5:00 P.M. on Sunday, April 24. Features will include demonstrations, lectures, raffles and bargains galore. Numerous dealers and manufacturers will be in attendance, and will be offering for sale a wide variety of hardware and software.

Admission is $3 in advance or $4 at the door. New or continuing members of P.A.C.E. will be admitted without charge, as will children under 14 when accompanied by a paying adult. Special room rates have been arranged at a nearby hotel. The Expo Mart is only 5 minutes from Exit 6 (Pittsburgh) of the Pennsylvania Turnpike.

For further information, please call (412) 486-4133, or contact P.A.C.E. at P. O. Box 13435, Pittsburgh, PA 15243.

How about the arangement:
7 8 9 7 8 9
u i o ==> 4 5 6
j k l 1 2 3
m , . 0 , .
to make a numeric keypad similar to most computers out there?

>
>David then enhanced the keypad operation by going to the convention that
>pressing the SELECT key and holding it down turned on keypad mode for those
>keys.

Why not use a SELECT+key to toggle keypad on and SELECT+key to toggle
it off again? Then you do not have to use one hand for the SELECT key
and you can use the keypad with whatever hand you desire.

>Of course
>key macro definitions per se are pretty flexible anyway In fact, if you did
>nothing more than add macro definition capability, and used SELECT to define
>the whole keyboard as a new character set, then of course one could define the
>keypad anyway he/she wanted to...

Perhaps use SELECT+a couple of keys to allow the user to have more than
one keyboard definition. SELECT+key1 turns on definition 1, SELECT+key2
turns on definition 2, etc. SELECT by itself could turn off all keyboard
definitions and return to normal.

> Anyone know or care?

I don't know about any of the newly-released-on-cartridge (or new, and on cartridge) games in particular. I do care, because I feel that owners of the "old" (400/800) Atari 8-bit computers should not be excluded arbitrarily. Certainly, if the game requires 64K, it's not going to run on a (stock) 400/800. If the program depends on specific changes to the OS (rev. B?) in the XLs/XEs, it won't run on a 400/800. But would Atari release a game that has such dependencies?

If your dealer(s) will let you try out the games in the store, why not just bring in your 800, hook it up (no disk since these are cart. games), and try the games? I've done this sort of thing with my first disk drive when a program would not load.

Of course! It's about Atari, I care!

I have it STRAIGHT from two horses' mouthes (and they both sell Atari
software/hardware, so it's not gossiping) that the XE Game System cartridges
will work with ALL Ataris with 48K. I don't know why you'd had problems with
Flight Simulator II, but apparently *all* of them will work on the 800!

This is terrific news, and is (hopefully) a sign that somebody up at
Sunnyvale is really on the ball.

--R.J.
B-)

P.S. I'd love to get Flight Simulator II alone, but right now it only comes
with the XE Game System...

I have a further, though simpler question. Are the
new el-humungo carts. the kind that requires the two little
plastic tabs on the computer to open the cart. or is the slot
exposed? I have the ICD MIO 130XE adapter which doesn't have
the plastic tabs. While this just means that I have to use a
paper clip to open the case every time I use an Atari brand
cart., I would rather not go through the trouble.

I've had an idea rolling around in my head for a while & I thought I'd post it up here & see what people think of it. A number of programs these days are starting to use shift-control sequences (I know of PaperClip and the Express! terminal programs). I think it would be neat to have an alternate keyboard that has these keys as seperate function keys. For example, S-C 1-0 could be F1-F10, S-C P could be print screen, etc. Making standards like this would help in software development since users wouldn't have to learn a whole new set of keys for each program. Opinions?

... add Kermit65 to the list... :-)

> it would be neat to have an alternate keyboard that has
> these keys as seperate function keys. ...

[details omitted for brevity]

This is indeed a good, and in fact somewhat workable, idea. The only limitation I see is that NOT ALL shift-control key combinations actually seem to generate hardware codes. (I may be mistaken. I know that not all SH-CTL combinations result in a character code reaching RAM shadow location 764 (decimal; hex 2FC), but it may be present in the hardware register whose location escapes me just now...)

Anyway, within that limitation, you should be able to do whatever you want with these key combinations, but some keyboard patterns may get bollixed if there's a "dead" key in the middle of it. Just be aware of this, and you should be "golden!".

This is news to me. Have they actually tried them? The reason I ask is
because Atari themselves (in the person of Neil Harris) said that many of
the new cartridges will not work in the older machines specifically because
they download 64K of information. After all, they are supposed to be for
the XE Game System which has 64K of RAM. Flight Simulator II has always
been used as an example of one of the cartridges that won't work unless
you have a 64K machine. I am curious also, because I would like to get
FS II when it is available.

Scott,

Something of this nature was posted in this very newsgroup not long ago. In fact, I think I still have it on file. Let me do a quick shell-escape and see, and if you're lucky I'll tack it on the end of this file.

* * *

* You're in luck. I found it! I haven't used it, 'cuz I don't have a trakball (buy me one and I'll be happy to test it for you! :-)) but it supposedly does the job!

Chris Chiesa

TAY ; Restore Y
PLA ; Restore A
RTI ;
END
```

Now - the interrupt vector and some other stuff needs to be set up.
I just do it in Basic.

```
5 F=100 ; Timer frequency - This value seems to work OK
10 OPEN #4,4,0,"D1:TRAK.OBJ" ; The binary of the above prog
20 GET #4,X:GET #4,X:GET #4,X:GET #4,X ; Strip the header
30 GET #4,X:GET #4,Y ; Length is in X (less than 256)
40 ADDR=6*256 ; Start of page 6
50 FOR I=ADDR TO ADDR+X
60 GET #4,X
70 POKE I,X ; Load image
80 NEXT I
90 CLOSE #4 ; Done
```

```
110 POKE 528,0:POKE 529,6 ; Set up $600 into timer interr vector
130 POKE 53761,0 ; Set volume to off - enables counter
140 POKE 53760,F ; Set up interrupt frequency
150 POKE 53769,255 ; Turn on timers
160 POKE 16,193 ; Enable timer1 interrupt
```

Now - a little program to test it

```
200 TRAP 200 ; Restart if coord's go offscreen
210 GRAPHICS 8+16
220 H=205:V=206 ; The coord's
230 POKE H,20:POKE V,20 ; Initialize coord's
240 PLOT PEEK(H),PEEK(V)
250 DRAWTO PEEK(H),PEEK(V)
260 GOTO 250
```

Good luck. Check for typo's (I don't think there are any, but who knows?)

True. Some S-C keys don't register anything in 764. Those would have
to be omitted. I am more worried, however, about the hardware side. First
of all, I would have to get details on how the current keyboard is
connected. Then I would have to find time to put it together. I don't know
if I could handle that. Therefore, if someone wants to develop & market this
idea, it is fine with me. Just be sure to send me a copy.

Why not just take the cartridge apart and remove the bottom part of
the cartridge leaving the case open? I wouldn't think that it would
be that hard to do.

>
> If nothing else, how about detailed instructions for making one?

I don't know of any commercial boxes, though I would think there would be some market for such a device.

However, a cousin of mine who is a video circuit design expert was helping a friend of his design such a box. My cousin decided that, while there are several commercial ICs that are used as NTSC decoders inside TV sets, they all seem to come out with a funny color balance when used on high-quality RGB monitors. He says TV picture tubes are designed to take something very similar to, but not identical with, true RGB inputs. There is some "matrixing" going on, i.e. the signals required at the grid pins of the TV CRT are some funny linear combination of the true RGB signals, and that is what the IC's all produce. If you build an NTSC decoder using the standard ICs, therefore, you get slightly fishy colors.

He concluded that the best thing to do was just whip up the decoder "from scratch", meaning using three balanced modulator ICs and his own carrier recovery circuit with PLL etc. I don't know if he ever finished the design, or coached the friend to the point of helping him finish it, but I'll try to find out and report back. If possible, I will try to get him to provide a schematic.

My cousin did comment that he had seen enough of an indication of the achievable resolution from the friend's early experiments (with fishy colors) to assure me that if I ever built such a circuit, I would "never want to go back to a composite monitor" on my Atari! Apparently, the resolution is pretty incredible.

For a quick fix, though, you might go buy a Commodore monitor and run it with separate chroma input.

Stephen Christian writes...
> A friend of mine was trying to put Frost Basic together the other
> day and found out he needed a program called SQUEEZE.COM (.com?)

> Could someone please forwarrd this program to me??

Are you sure that SQUEEZE.COM is what is needed? When I distributed FrOst BASIC from the disk that Ulrich Lange sent to me from Germany, it was encoded with SHRINK, as I recall. I have SHRINK, SCRUNCH, and DISKCOM, but no SQUEEZE in my files. I think "SQUEEZE" is also the name for one of the encoding techniques used in ARC.

If there really is a disk compression program called SQUEEZE.COM, I would like to get a copy of it just to make my files complete.

Finally, if all else fails, I could e-mail you FrOst BASIC, SHRINKed and uuencoded, along with SHRINK (and uudecode if you need it) to decode it with.

For those who didn't see the original posting(s), FrOst BASIC is a very nice enhanced BASIC for the older 400/800. It is Public Domain. There is also an updated version for the XL/XE called Turbo BASIC, which includes a Compiler!

1124. My little project

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-15 15:39:41 UTC
From: gdtltr@vax1.acs.udel.EDU
Message-ID: <1042@udccvax1.acs.udel.EDU>
Source record: 116978

Well, I have finally gotten ACE C and CC8 & have
done some testing. The primes program provided with
ACE C runs quite a bit faster. However, in doing my
own programming, CC8 seems much more reliable.
Several times I have tried compiling a perfectly
good C program with ACE & it just freezes up on me.
Since the screen is automatically turned off you can't
see what is going on. CC8 almost always works correctly
and you have the option whether or not you want to have
the screen turned off. Note: my copy of ACE C might be
bad. Has anyone else had these problems?
The programming project I spoke of earlier was a
Plato terminal emulator. I don't know about anywhere
else (except UIll Urbana), but Plato is used a lot
here at the U of D. Atari makes an emulator cart.,
but it only works with the 850 & it costs money. I
intend to change their mistakes. For reasons of
speed, I may have to write parts of it in assembly
language (probably LADS, since that's what I have)
for reasons of speed, but most of it will be in C.
Since CC8 is more reliable, I plan to use it most of
the time. I will probably make it a Shareware deal
(guilt-trips & all that) but I haven't decided yet.
If anyone is interested in this idea, let me know.
I will be interested to hear your ideas & I may need
some beta-testers in a couple months.

That is a true point. However, near as I can tell (or remember -- Direct
quoting is not one of my talents B-), the XE Game System cartridges should be
able to work on the older 800 machines. I do know that I haven't heard anyone
confirm any reports of INcompatability...

But like you said, the 64K cartridges may *not* work, because of insufficient
RAM. Since I am beginning to have doubts myself on this matter, lemme go check
this out again, and get back to you...

--R.J.,
feeling embarrassed

1126. Some XE software runs on XL

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-16 20:57:42 UTC
From: charles@c3engr.UUCP
Message-ID: <2491@c3engr.UUCP>
Source record: 116980

While browsing in the Commodore section of Babbage's recently (their Atari 8-bit section is pretty sparse, and I've noticed several titles packaged for both C64 and Atari), I noticed "Gateway to Apshai" for only $3.99. The only hitch was that it was for the Atari XE, and I have an XL. But I thought it would give me an incentive to finally get going on one of those compatible memory upgrades, so I got it anyway.

When I got home, it occurred to me that if it ran on a 64K Commodore, why would they need the extra memory of an XE? To my knowledge, that's the only fundamental difference between the XL and XE, so I began to wonder how it would fail to run on my machine.

Anyway, the game seems to run just fine, which leads me to wonder: a) How much "XE" software is there that will run on an XL, and: b) Why wouldn't the manufacturer state "XL/XE" on the package?? Wouldn't that only increase his sales?

Of course, the bad news is, I just lost my incentive to upgrade...

>the manufacturer state "XL/XE" on the package?? Wouldn't that only increase
>his sales?

All we're talking here is a problem in packaging. Epyx probably put "XE"
on the box because that's the only 8-bit Atari they know of. Besides, there
is the 64K 65XE (which is an 800XL in a new case B-).

Usually, if a program requires all 128K of the 130XE, it will specifically
say so on the back of the box. Most programs, however, are written to see
how much RAM you have, and configure itself accordingly (Typesetter, for
instance, comes with a 64K version and a 128K version)...If it just writes
"For the Atari XE", that's equvalent to saying "*NOT* for the ST line".

Don't panic, somebody in packaging just screwed up a tad.

Also the X-Lent word processor pgm.

> it would be neat to have an alternate keyboard that has
> these keys as seperate function keys. ...

[details omitted for brevity]

This is indeed a good, and in fact somewhat workable, idea. The only
limitation I see is that NOT ALL shift-control key combinations actually
seem to generate hardware codes. (I may be mistaken. I know that not
all SH-CTL combinations result in a character code reaching RAM shadow
location 764 (decimal; hex 2FC), but it may be present in the hardware
register whose location escapes me just now...)

No, you're not mistaken, at least about the symptom. I've never gotten
to the bottom of the root cause, either, but my guess is that the real
low-level key-scanning logic gets confused by some combinations of c-sh-
things, and concludes that there was really no keypress. Esp given that
the the nonfunctional keys are in sort of a regular pattern, that seems
more likely than that somebody actually filtered them out in the
interrupt-level software.

Anyway, within that limitation, you should be able to do whatever you
want with these key combinations, but some keyboard patterns may get
bollixed if there's a "dead" key in the middle of it.

True, but it's worse than just holes. As I recall, you lose Tab thru
'R', and 'H' thru '|', ie there are two substantial horizontal chunks
taken out of the keyboard. That makes it real tough to do, say, a fake
VT100 keypad. I know, as I tried real hard to get that to work when I
did the last version of Kermit65.
Just be aware
of this, and you should be "golden!".

I sent mail last summer about the problem, but didn't get any feedback
about any workarounds. Anybody got any better ideas these days?

1130. Re: vt100 emulator key definition standards

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-17 22:50:41 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8804172250.AA11495@mitre-bedford.ARPA>
Source record: 116984

Steve Klassen's suggestions (latching the keypad on, having multiple keypad definitions available, etc.) sound useful to me. For a single keypad, it occurred to me that (assuming it can be read by the software) SHIFT-SELECT could be used to lock the keypad mode, while SELECT plus a keypad key could act the way OmniCome does now, i.e. keypad mode is activated only while the SELECT key is held. This would be a true "upward compatible" upgrade from the OmniCom convention.

With this convention, touching the SELECT button would unlock the SELECT mode.

This very much in the spirit of the way the SHIFT and CAPS keys work, or the SHIFT and SHIFT LOCK keys on a normal typewriter. Because of this, I think it would instantly feel completely natural to current users of OmniCom, as well as to those who had not previously used it.

I believe KERMIT65 will get a key definition capability soon, but probaby will use the OPTION key to perform the function that OmniCom uses the SELECT key for, since SELECT has been assigned a function already in KERMIT65. (Of course, John Dunning might decide to reverse the convention for compatibility, since KERMIT is still not finalized.)

As for the multiple keypad definitions, John D. is mulling over ideas like this right now (I hope!). If he chooses to support several different keypad maps simultaneously, I'd suggest something like a CONTROL key pressed while in keypad mode, e.g. SELECT-CTRL-1 for keyboard definition 1, SELECT-CTRL-2 for defintion 2 etc. (Using the SELECT key for consistency with the above -- it might all use the OPTION key if John keeps it that way.) In this framework, SHIFT-SELECT (or OPTION) would put the terminal in keypad mode, CTRL-1 would select definition 1, and SELECT (or OPTION) would drop back out of keypad mode but retain the definition 1 layout.

Anybody else have suggestions for vt100 emulator standards or conventions?

From: pjd@mandrill
Message-ID: <2426@mandrill.CWRU.Edu>
Source record: 116986

I hope the XF551 is available! I ordered one from Lyco
and they claim that the 551 is in stock. (Won't be either
the first or last time that I've been lied to, however :-)
It is shipping WITHOUT the new Atari operating system and
this may pose a problem for me as I only have copies
of 3.0 and 2.0 (not even 2.5!)

After thinking about the 551 pricing, $180 isn't too
outrageous given that the drive, power supply, case,
controller, etc. add up to about $140-$150. Kick in a
fair profit to all parties concerned and $180 isn't too bad.

What are the recommendations for a true double-side
operating system? I'm not partial to menu driven stuff,
so a command line interpreter is prefered (and then,
bride of Unix is prefered over son of MS-DOS.)

Thanks, as they say, in advance....

> True, but it's worse than just holes. As I recall, you lose Tab thru
> 'R', and 'H' thru '|', ie there are two substantial horizontal chunks
> ....
Hmmm... "Tab thru 'R'" implies that W and R don't work with <CTRL><SHIFT>.
Yet, the ACTION! editor uses these along with other <CTRL><SHIFT> combinations.
(It has used such combinations since ACTION! first appeared, as far as I know.)
How does it work, if the key combo's don't generate any codes?

Do you mean the *May* issue? That's the one I just received a few days ago. There was only one aspect that I was disappointed with- the advertising. There was almost none to speak of. Normally, that would be a plus, except that with how hard it is to find Atari stuff in stores, I rely on the mail order places advertising in Analog and Antic. Anybody know what the scoop is on the lack of advertising in this issue?
Oh yes, also...the "Busy Buddy Express" program listing is something I'd definitely like to have. BUT...I just typed it in before, and while it seems to work fine with Atari Dos 2.5, it does NOT work with SpartaDos (at least not 2.3). Under Sparta, it loads and appears to "work", but control never gets returned to DOS, hence you can't load Express! Anybody else confirm/deny this? And has anybody found a fix to make it work with Sparta is this is the case?

1139. XF551 & SEGA GUN

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-19 14:56:00 UTC
From: CL206601@ULKYVX.BITNET
Message-ID: <8804191503.AA16900@ucbvax.Berkeley.EDU>
Source record: 116993

Hello ALL

Its been a while since I posted anything to comp.sys.atari.8bit.
But i have kept up with the latest postings. Well I recently bought a
xf551 disk drive, And I'm wondering if anyone has written a program for it
that will read txt files off of 360K ibm disks? I have included a mod
for converting the sega light gun to working with the XE/XL/800/XEGs.
I can dispell some of the rumors about the xf551.

1) It can read 810SSSD or 1050 dsdd 40 tracks floppys.
2) Spartados or another DS dos is required.
3) It is still packaged with DOS 2.5(ATARI Wheres ADOS!)
4) It is only slightly faster than a standard 1050 with Sparta or
DOS 2.5
5) It has no problems load flippie software.(c64 front/Atari Back)

Even Tho I feel I payed too much for the drive it is a valuable addition
to my atari hardware.
Post any quires to the net.

The following was captured from The ATARI SCENE Lousiville KY BBS.

------Cut here for Sega mod----------

OK YOU HOZERS, HERE IS THE SEGA LIGHT GUN MOD. I HAVE HAD THIS MOD SINCE
LEFTY FIRST GOT HIS XEGS (ONE OF IF NOT THE FIRST ONE IN DENVER!!) SO I ADMIT
I'M A LITTLE SLOW WITH TYPING THIS UP. BUT HEY, YOU TRY RUNNING A BBS AND
GOING TO SCHOOL AND WORKING A CONSTRUCTION JOB AND GOING TO CHURCH
THREE TIMES A WEEK! BUT AT LONG LAST, HERE IT IS. JUST SO YOU KNOW IT WILL
REALLY WORK, WE HAVE DONE A MESS OF THEM ALREADY.

FIRST BUY YOURSELF A SEGA LIGHT GUN, AND AN ATARI JOYSTICK EXTENSION CORD.
GET THE CORD AS SHORT AS YOU CAN, THE LIGHT GUN WILL HAVE AN AMPLE LENGHT FOR
THE GUN.

OK, OPEN THAT PUPPY UP. ONE OF THE STICKERS WILL HAVE TO BE REMOVED, THERE
WILL BE A SCREW UNDER IT. DON'T LOSE THE LENS WHEN YOU TAKE THE GUN APART,
YOU MIGHT KINDA NEED THAT. OK INSIDE WHERE THE TRIGGER FLIPS A SWITCH THERE
IS A BOX WITH 2 LEADS ON THE BACK SIDE. THE WIRE SOLDERED ON THE LOWER ONE
NEEDS TO BE PUT ON THE UPPER ONE. THAT IS OFTEN EASIER SAID THAN DONE, SINCE
SEGA GETS ITS KICKS APPARENTLY BY BREAKING OFF THE UNUSED ONE. JUST BE
SURE YOU GET A GOOD SOLID SOLDER ON IT. OK CLOSE THE GUN UP, YOU ARE DONE
INSIDE OF IT. NOW, CUT YOUR JOYSTICK EXTENSION CABLE IN HALF. FIND OUT
(PROBABLY BY USING AN OHMMETER) WHICH WIRE IS #7 FROM THE MALE SIDE (THAT IS
THE END THAT PLUGS INTO YOUR COMPUTER). IT IS USUALLY A GREY WIRE, BUT BE SURE.
WHEN YOU FIND OUT, RECONNECT IT TO ITSELF. THAT WILL BE YOUR GROUND.

OK LET'S TAKE A LOOK AT THE CABLE:

MALE END FEMALE END

1 2 3 4 5 5 4 3 2 1
6 7 8 9 9 8 7 6

REMEMBER THE FEMALE IS JUST A MIRROR OF THE MALE END! OK, YOU WANT ONLY THE FOLLOWING 4 CONNECTIONS MADE:

MALE WIRES FEMALE WIRES
1 8
7 7 (OUR GROUND)
8 9
9 5

AND THAT'S ALL THERE IS TO IT. YOU NOW HAVE A SEGA GUN THAT CAN BE EASILY RE-CONVERTED BACK TO A NORMAL GUN BY UNSOLDERING AND RESOLDERING ONE WIRE INSIDE. THIS GUN IS REVIEWED AS BEING FAR MORE ACCURATE THAN EVEN THE ATARI GUN IN ANTIC MAGAZINE. I MYSELF WOULD RATHER HAVE AN ATARI GUN BECAUSE IT SAYS "ATARI" ON IT (ANYONE OF IMPORTANCE LISTENING OUT THERE???) BUT SINCE ATARI WON'T SELL ME ONE, BUT WILL SELL ME LIGHT GUN GAMES, I AM GLAD THE SEGA WAS SO EASILY CONVERTED. FOR YOU BASIC PROGRAMMERS, YOU CAN USE THE LIGHT GUN AS SIMPLY A LIGHT PEN IF YOU WISH. THE X LOCATION IS FOUND BY PEEK(564), THE Y LOCATION IS PEEK(565). THE TRIGGER IS STRIG(0), IT NORMALLY RETURNS A 14 (JOYSTICK UP) BUT WHEN YOU PULL THE TRIGGER IT RETURNS A 15 (JOYSTICK CENTERED). I'D LIKE TO SEE A NICE SHOOTING ARCADE GAME, BUT THE ATARI LIGHT GUN IS STILL NEW SO WHO KNOWS WHAT THE FUTURE MAY HOLD. BUY LOTS OF LIGHT GUN GAMES AND MAYBE ATARI WILL GET THE IDEA!

COMPLIMENTS OF HOZERVILLE BBS, (303)/933-0906 24 HOURS 20 MEGS 300/1200/2400 BAUD SYSOP JACEY SQUIRES.

Command]

I just got my XF551 yesterday.

I must say I am quite impressed. I promptly unplugged the 5.25" mechanism and stuck a 3.5" 720K in; no hitches, but I haven't tried formatting it to 720K yet (I wonder if the controller can handle the Percom control codes). I'll get around to it this weekend.

One thing that would have been nice is if Atari included an ST floppy connector on the back, making the drive dual usage, ala SX212 modem. Probably would only have cost about $10 to add, and I will probably do it so that I can use the drive on both the ST and the 8 bit, and have a 5.25" drive that matches the ST case.

Recommended DOS: I prefer SpartaDOS. It formats most popular formats, if the drive you are using recognizes the Percom codes. It works with Ultra Speed on both US Doubled and Happy 1050s (the Happy is quite a bit faster) and the new version should support Indus and XF551 as well.

My XF551 came with DOS 2.5.

I am a real SpartaDOS fan myself. I don't know if the format program itself supports double sided drives, but I can almost guarantee that there is something that will do the job on ICD's BBS. MyDOS will work with the 551 right away, but I tend to prefer Sparta overall. You may even get more file space because of the way SpartaDOS formats the data. It has been said before, but please remember that you can not use "flippy" disks with an' unmodified 551. You will either have to get the drive modified or just use the special double sided format to take advantage of both sides.

Heres some answers to misc. questions that have cropped up on the net lately, and a few questions and comments of my own. Some of the questions may have been answered by the time my message is posted, Due to the links to ohio-state going down regularly!

****
Analog-misc**********
****
I have the May issue of the Mag and it is better than the april issue. I would like to see the conclusion on the atari Zucchini article, they claim they have figured out how to connect 8-bit machines using the SIO port. Even tho analog is going down hill it is still better than ANTIC! for 8-bitters.

Does anyone have the ANALOG 8-bit extra, it supposedly has all those programs that were to large to publish in the magazine. Also it supposedly had lots of ACTION! programs in it?

****
Software_misc-**********
****
Desktop video type software is available for the 8-bits the titles i have seen are virtuoso by virtuosonic, Colour space from Antic and Envision also in the antic catalog. Virtuoso has been reviewed in recent issues of Antic and Analog mag.

The availibility of software is a problem atari should address for the 8-bits. Yes its great Atari has made those super 256K carts for games like Flight simulator II. But I'm still waiting for them to release something new. If the future of the 8-bits depends on the XEG Atari should be working a little bit harder to move some software titles. Atari should contact Micro-Prose(old name) and get them to convert some of there games to the cart format. Especially the ones they never released. MindScape is another good target for new games. Those new XE carts work just fine on the 800xl. Games labeled for Xe usually work on the Xl machines if they don't require 128K, but if you have a 256K Xl then i only can think of one program that doesn't work, it is a destop publishing program. By the way if you still have an old 800 you should at least compliment it with an xl or Xe machine, merely for the fact you can find one used for around $25-$70.

The super carts are a good idea i wonder if ADOS will be in one? I'm sure atari could cram a window/icon/mouse environment into a 256K cart, leaving most of our 64K available for Programs. IF ADOS ever leaves the vapor world maybe applications programs will

be written. Hopefully atari will make ADOS compatible with the 256K+ ram upgrades. Also I would like to use The MIO with it.

****
Hardware-misc**********
****
I have seen prices for the Xf551 run from $150-$199. They are available in Louisville Ky, so the must be available in other remote parts of the country.

I have seen the sx212 modem working on the sio port with a PD program called SX212 companion, which modifys your version of 1030 express to work with the sx212. SX212 companion also loads a handler that allows kermit65 or other term programs to use the sx212.

I have a Track ball demo programs in ACTION! and Basic.
(Scott @ ksuvm.bitnet) Send me e-mail or talk real-time over bitnet using the send command!

Now that I have posted a mod to convert the Sega light gun to work with the ATARI, there should be a mod allowing the Sega 3-d glasses to work with the 8-bits coming soon. Most of the mod would probably be in the form of software and maybe the construction of an adapter cord,(since sega moved some of the signals around the 9 pin din). Too Bad atari does not sell the Flight Sim II cart or the light gun separately, some one just might buy them.

Last but not least Here in Lousiville Rumours of atari losing money are floating around among the Computers dealer that are left around here. But we haven't had an Atari dealer for about 2 yrs.

There's a place in Marion, IN, called "Computer Corner" (gave the business card to a friend of mine, else I'd post the phone number), which received several XF551 drives about a month and a half ago. They may or may not have any left, but that's beside the point: I saw 'em with these own eyes, and touched 'em with the very fingers I'm using to type this. They're real. This batch, at least, shipped with a copy of, I believe, DOS 2.5. I'm not entirely sure; write to my buddy 'aegnor' at this node (see .signature, below), as he usually keeps better track of that stuff. Same goes for pricing info; ask HIM!

From this, I'll infer that this drive acts closest to PC type drives.
If this is true, we should be able to build 3.5" drives using the
XF551 or 551 repair parts. does anyone know if B&C or AmericanTV
are selling XF551 parts? It would be great if an "upgrade" for the
1050 drive were possible.

The drive in XF551 is the same interface as an IBM PC/XT drive. When
pulling a drive out of an IBM, all one must do to get it to work in the
XF551 is change the drive select jumper.

The XF551 also uses normal mounting holes on the side of the mechanism.
The 1050 used the less common holes on the bottom of the mechanism.

I don't know when anyone will be selling parts for the drive--it took the
local places quite a while to get 130XE parts after the 130XE came out.

I think many advertisers are quite pissed at Analog. Back in August,
we contracted for the November issue (Christmas ads...). We were
never notified when the issue did not come out. Then, when they
finally put one out in April... There was our November ad. They
never told us it was coming out, or ask if we wanted to use the
same ad or even if we still wanted to be in it. Didn't even
get a copy of the magazine. Just a bill for an insertion in the
April issue when we never ordered one!

For one thing, we had a price increase and there is an ad we
didn't want with last year's pricing....

Great way to keep advertisers happy...

Yet, the ACTION! editor uses these along with other <CTRL><SHIFT> combinations.
(It has used such combinations since ACTION! first appeared, as far as I know.)
How does it work, if the key combo's don't generate any codes?

Well, probably I got the details wrong. I don't have my notes from
doing Kermit in front of me, so I probably misremembered exactly which
sections are busted. I do clearly remember that there are two sections
of the keyboard, one approximately on the left half, one on the right,
and separated by one row, that don't generate anything with c-sh-.

Source record: 116805

Does anyone out there know if it is possible (or have an algorithm)
to read IBM PC MSDOS diskettes on an Atari 1050 floppy disk drive.
I'm looking for a way to transfer files which come over the NET to
my modemless Atari 800xl at home.

I'm hoping that with sufficient knowledge of the directory structure,
one could use a few BASIC GETs to retrieve the data. I'm wondering
about the formatting though and what that really means. Anybody
done this sort of thing?

/keh

\d2
\addiidoc.4\
\\S[0-9 or A-K] - CHANGE SPACING

Use this command to change character spacing for any text
following the command. To change to 0-9 columns use 0-9. For
10-20 columns, use A-K (A is 10, B is 11, K is 20). Spacing can
be changed anywhere in a document.

EXAMPLE:

YOU TYPE:
G\\s0r\\s1a\\s2d\\s3u\\s4a\\s5l\\s6l\\s7y
I\\s8n\\s9c\\sar\\sbe\\sca\\sds\\sei\\sfn\\sgg\\si.

DDII OUTPUT:
G\s0r\s1a\s2d\s3u\s4a\s5l\s6l\s7y I\s8n\s9c\sar\sbe\sca\sds\sei\sfn\sgg\si.\s2

\\L - BLOCK LEFT

This command sets the alignment mode to block left for the
current line and following lines. This command turns off
centering, block right, and justification.

EXAMPLE:

YOU TYPE:
\\lThis is normal, block left text.

DDII OUTPUT:
This is normal, block left text.

\\C - CENTERING
```

Use this command to center any text following the command on the current line and all following lines. If the line is too long to be centered it won't be adjusted.

EXAMPLE:

YOU TYPE:
\\cThis line is centered.

DDII OUTPUT:
\cThis line is centered.
\l

\u12/87\cDAISY-DOT II\rPage 13\u
\l

\l\\R - BLOCK RIGHT

This formatting command blocks the text following the command in the same line and all following lines to the right margin. The line won't be changed if it is too long for the current right margin.

EXAMPLE:

YOU TYPE:
\\rThis line is even with the right margin.

DDII OUTPUT:
\rThis line is even with the right margin.

\lCOMBINING BLOCK LEFT, CENTERING, BLOCK RIGHT

Commands for block left, centering, and block right may be all combined on one line, useful for page headers:

EXAMPLE:

YOU TYPE:
\\lBlock Left\\cCentered\\rBlock Right

DDII OUTPUT:
Block Left\cCentered\rBlock Right

\l\\J - JUSTIFICATION

This command justifies the current line and any following lines. To be used effectively, every line of text should normally be a little shorter than the right margin. For example, to use justification with the Roman font, using a left margin of 10, a right margin of 70 (from your word processor), spacing of 3, and setting the DDII right margin to 1" will produce nice justified text with 1" margins on each side.

Since the last line of a paragraph of justified text should never be justified, the block left command must be used in conjunction with the justify command (included at the end of the

paragraph):

EXAMPLE:

YOU TYPE:
\\jDaisy-Dot II Print Processor can justify text so that the
left and right margins are even. The last line of every
justified paragraph should not be justified, and DDIIPP's block
left command easily takes care of that.\\l

\u12/87\cDAISY-DOT II\rPage 14\u
\l

DDII OUTPUT:
\jDaisy-Dot II Print Processor can justify text so that the left
and right margins are even. The last line of every justified
paragraph should not be justified, and DDIIPP's block left
command easily takes care of that.\l

\\M[0-9 or A] - RIGHT MARGIN

Use this command to change the right margin for the current line
and all following lines. Use 0 if you want no right margin, 1
for .5", 2 for 1", 3 for 1.5", 4 for 2" and so on. Use A for a
right margin of 5".

EXAMPLECertnIn gggggggggggggggggggggggggggggfbn\o\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\
\\\7tl\m5\\rText blocked right
with 2.5" margin.
\\m8Block right with 4" margin

DDII OUTPUT:
\m5\rText blocked right with 2.5" margin.
\m8Block right with 4" margin.

\l\m2\\B - BOLDFACE

This command toggles line boldfacing on or off for the current
line and all following lines. Only entire lines can be printed
in boldface.

EXAMPLE:

YOU TYPE:
\\bThis line is in boldface.
\\bThis line is normal.

DDII OUTPUT:
\bThis line is in boldface.
\bThis line is normal.

\\W - DOUBLE WIDE

This command toggles wide print on and off for all text
following the command.

EXAMPLE:

YOU TYPE:
You can mix \\wdouble wide text\\w with normal text.

DDII OUTPUT:
You can mix \wdouble wide text\w with normal text.

\u12/87\cDAISY-DOT II\rPage 15\u
\l

\\U - UNDERLINE

This command toggles underlining on and off for text following the command. DDIIPP underlining is continuous, meaning that spaces between underlined words are underlined too.

EXAMPLE:

YOU TYPE:
With DDII you can easily \\uunderline text\\u.

DDII OUTPUT:
With DDII you can easily \uunderline text\u.

\\A[Dn:FILENAME.EXT]\\ - APPEND FILE

Use this command to chain text files together. The command may be anywhere in the file, as long as it is alone on a line (no other text on that specific line). The easiest way to do it is place it in blank lines within your text file. The file to be appended must exist as the filename you typed in.

The append file command can chain many text files. For example, the original file may have a command to append a second file, and the second file may include a command to append a third file, and so on.

The append file command is recognized when selecting different pages to print. For example, suppose you have two files: A is 5 pages long and includes the command to append file B, which is also 5 pages long. When printing file A, if you specify to print page 10, the last page of file B will be printed.

TAB COMMANDS

DDIIPP has three commands for using proportional tabs for aligning tables, charts, etc. These tabs should be used completely independent of tab functions in your text/word processor, because those tabs are not designed for proportional text and everything turns out misaligned.

\\P - POSITION TAB

This command sets a tab at the current column position. Tab positions are set before lines are centered, blocked right, or

justified (they are always set as if the line is blocked left).
There may be up to 10 tabs set at one time.

\u12/87\cDAISY-DOT II\rPage 16\u
\l

\\T - EXECUTE TAB

This command tabs (adds space) to the nearest tab stop as positioned with the \\P command. If you try to tab past the number of tabs you have previously set, DDIIPP will tab to the right margin.

\\E - ERASE TABS

Use this command to erase all tab settings.

EXAMPLE 1:

YOU TYPE:
```
\\eNAME: \\pAGE: \\pSEX:
Cathy Cook\\t28\\tFemale
Jim Jones\\t23\\tMale
Amy Allen\\t69\\tFemale
Mark Miller\\t54\\tMale
```

DDII OUTPUT:
```
NAME: \pAGE: \pSEX:
Cathy Cook\t28\tFemale
Jim Jones\t23\tMale
Amy Allen\t69\tFemale
Mark Miller\t54\tMale
```

EXAMPLE 2:

Note how there is an extra tab at the end of each line. This sets the length of every line equal, allowing correct centering or blocking right of text with tabs:

YOU TYPE:
```
\\e\\cNAME: \\pAGE: \\pSEX:\\p
Cathy Cook\\t28\\tF\\t
Jim Jones\\t23\\tM\\t
Amy Allen\\t69\\tF\\t
Mark Miller\\t54\\tM\\t
```

DDII OUTPUT:
```
\e\cNAME: \pAGE: \pSEX:\p
Cathy Cook\t28\tF\t
Jim Jones\t23\tM\t
Amy Allen\t69\tF\t
Mark Miller\t54\tM\t
```

\l\\V[Dn:FILENAME.EXT]\\ - INCLUDE FILE VERBATIM AND \\N - NEW PAGE

Use these commands to include any file byte for byte within your text. The main use is for including pictures within the text.

\u12/87\cDAISY-DOT II\rPage 17\u
\l

A public domain program called Billboard by Chris Wareham and corresponding documentation are on Side 2 of the DDII disk. It prints out MicroPainter pictures in an infinite number of sizes. In order that you are familiar with references in the upcoming paragraphs, please print out the Billboard documentation with DDII or by copying it from DOS, using "P:" as the destination filename.

Mr. Wareham wrote Billboard for Epson printers and it isn't compatible with Star printers. However, in the Billboard documentation he describes the printer codes used and how to change them for other printers; you can refer to your printer manual and convert it for Star printers. Contact me if you need help doing so.

To create a picture file for DDII using Billboard, choose PRINT from the menu. You are prompted with a small modification I have made, allowing output to different devices; since you want the picture dumped to a disk file so it can later be included using the \\V command, type in the name of this disk file you want output directed to. If you want it to print to the printer, type "P:". From Billboard's many size options, a vertical, single height, single width, 720 dpl, centered setting is most practical although you can really use any combination you desire.

The file created by Billboard is then ready to be used from DDIIPP. Somewhere in the line directly preceeding where you want the picture to be included, use the \\V[Dn:FILENAME.EXT]\\ command. After that line is printed the file specified by the \\V command, which must be in the correct drive, is "copied" directly to the printer. After the file has been copied to the printer, DDIIPP continues with printing the text file.

In general, you should know the vertical size of the included picture since DDIIPP doesn't examine the contents of the file. Billboard single height pictures are about 16 standard lines high. Whatever the size, the page length for the page with the included picture should be set for the standard 66 lines minus the length of the picture minus a couple of lines to be safe. For example, assume you are including two single height pictures on a page. The number of lines for that page should be set from your word processor as 32 (66-2-2*16). Since DDIIPP keeps track of pages based on 66 lines per page, including a picture throws

off the line count. To solve this problem, used the \\N command. This command forces a form feed and resets the line count. The \\N command must be alone on a line and should follow the last line of a page with graphics. The new page command is recognized by the page select options to ensure correct pagination.

Make sure that pictures never cross top/bottom margins.

The Verbatim command is not limited to pictures. One other possible use is to include text printed in the original typestyles of your printer.

\u12/87\cDAISY-DOT II\rPage 18\u
\l

DDIIPP QUESTIONS AND ANSWERS

Q: I own a Star printer and set the renamed the STAR.CNF file to STAR. But when I print, the lines are too close together. What's wrong?

A: You are using one of the newer Star printers that is 100% compatible with Epsons. Configure DDIIPP for Epsons instead.

Q: I own a Star Gemini 10X. I configured it with the STAR file, but I only get garbage whenever I print. What's the problem?

A: Based on a few rare cases throughout the country, it seems that some older Gemini 10X are incompatible with DDII. However, most Gemini's work fine.

Q: How can I put the DDII fonts in my Ramdisk?

A: There are two methods for doing this. 1) Exit DDII and go to DOS, from where you can copy any desired files into the RAMdisk and then reload DDIIPP. 2) Use a boot file (such as RAMCOPY! from Analog issue 44, July 1986) or a batch file that automatically copies desired files to a RAMdisk.

Q: It would be a lot easier if I could use a word processor and DDIIPP at the same time without having to reboot. Is there a way to do this?

A: Yes, especially if you have a RAMdisk. Copy the DDIIPP AUTORUN.SYS file to the RAMdisk, and also copy a word processor that doesn't require to be booted (such as Textpro) into the RAMdisk. You can then instantly exit one and run the other.

Q: I would like more examples of how to use the DDIIPP local formatting commands. Can you help?

A: The DDII documentation files are full of formatting commands. By copying these files from DOS, using "P:" as the destination filename, you can get printouts of these files and see every

embedded command along with the rest of the text.

Q: When I include many commands on one line, my word processor formats the line in such a way that it is much too short when printed from DDIIPP. Can I do anything about this?

A: The problem you mention occurs when long commands are embedded within a block of text; in most cases, this isn't a problem. Because the word processor has no way of knowing what characters in your file are DDIIPP commands, the text is

Thanks for the response on the 551. UPS delivered mine on 4/19 (Tuesday)
in good shape. (Thanks Lyco - seven day turnaround.)

Yes, it ships with 2.5. The documentation is confusing as the specification
section in the 2.5 manual claims single sided operation (128K bytes.)
Hmmm.... Is this a typo Atari?

I enjoyed news of the 3.5" disk hack. I like this format better than
5.25 inch and will try it eventually. Keep those cards and letters
coming!

As I also have a 520ST, alternate use on the ST sounds good, too!
Maybe a shared disk? :-) Sure would make file transfers hum along.

Thanks, again, for the operating system recommends.

Does anyne know of any Desk Top Publishing software for the 8-bit
other than "Typesetter" and "News Companion".

Out of these two, I prefer Typesetter, but they both require you
to re-type the "article" if you want it formatted differently.
And use "Plates" [Typesetter doesn't but I use 2 files for a full page]
for the output. They also both use single density ONLY for the
files [ACK!]... Limiting 3 "plates" per Single Sided diskette.

I have seen "Newsroom" by Springboard, for the Apple IIe, ETC...
Hasn't anyone done something similar for the ATARI??

Oh. While I'm here, can anyone recommend a repair-place for some
sick RANA 1000 drives??

jgroves@hawk.ulowell.edu

NO! I don't have a .signature. What's it to you?

Subj:
greetings...

A friend of mine has an Atari 800, which we are trying to use to
access our local VAXCluster. We are in need of some way of hanging
an RS232 port off this machine.
Is there somewhere that still sells 850's? As an alternative, as
money is scarce, can we purcahse a add-on that provides just the R:
device?
Does anyone have schematics for a quick-n-easy project to provide
an RS232 port?
Any help would be appreciated.

Please respond directly to me, as I am not subscribed to this
discussion...

Last I heard, Newsroom was just being released for the Atari
8 bit computers. The port over was brought about by a massive
letter-writing campaign started by Antic magazine. Apparently
it worked. Antic promises to review Newsroom as soon as they
can get a copy (plus the 3 month publishing delay).

Funy you should mention Newsroom, because it's just been released for the
8-bit Ataris. Straight from my Atari soft/hardware salespeople friends...

And for those who I left hanging on the topic of "which XEGS carts won't
work on a 48K 800?", the official word is in:

Will NOT work on a 48K 800:
Flight Simulator II (awwww)
Lode Runner
David's Midnight Magic

Will work on a 48K 800:
Everything else

Hope this helps,

I seem to remember a PD driver that was available that would do the same
thing. And it worked quite well. I believe it was given away by Batteries
Included to work with their PaperClip and it did the same for a number of
other packages.

Message-ID: <8804251748.AA09079@ucbvax.Berkeley.EDU>
Source record: 116823

Heres some answers to misc. questions that have cropped up on the net lately, and a few questions and comments of my own. Some of the questions may have been answered by the time my message is posted, Due to the links to ohio-state going down regularly!

****
Analog-misc**********
****
I have the May issue of the Mag and it is better than the april issue. I would like to see the conclusion on the atari Zucchini article, they claim they have figured out how to connect 8-bit machines using the SIO port. Even tho analog is going down hill it is still better than ANTIC! for 8-bitters.

Does anyone have the ANALOG 8-bit extra, it supposedly has all those programs that were to large to publish in the magazine. Also it supposedly had lots of ACTION! programs in it?

****
Software_misc-**********
****
Desktop video type software is available for the 8-bits the titles i have seen are virtuoso by virtuosonic, Colour space from Antic and Envision also in the antic catalog. Virtuoso has been reviewed in recent issues of Antic and Analog mag. Datasoft also has an entry in this arena with a video tape titler, I'm not sure of the exact name of the software but it costs around $40.

The availibility of software is a problem atari should address for the 8-bits. Yes its great Atari has made those super 256K carts for games like Flight simulator II. But I'm still waiting for them to release something new. If the future of the 8-bits depends on the XEG Atari should be working a little bit harder to move some software titles. Atari should contact Micro-Prose(old name) and get them to convert some of there games to the cart format. Especially the ones they never released. MindScape is another good target for new games. Those new XE carts work just fine on the 800xl. Games labeled for Xe usually work on the Xl machines if they don't require 128K, but if you have a 256K Xl then i only can think of one program that doesn't work, it is a destop publishing program. By the way if you still have an old 800 you should at least compliment it with an xl or Xe machine, merely for the fact you can find one used for around $25-$70.

The super carts are a good idea i wonder if ADOS will be in one? I'm sure atari could cram a window/icon/mouse environment into

a 256K cart, leaving most of our 64K available for Programs. IF ADOS ever leaves the vapor world maybe applications programs will be written. Hopefully atari will make ADOS compatible with the 256K+ ram upgrades. Also I would like to use The MIO with it.

****
Hardware-misc**********
****
I have seen prices for the Xf551 run from $150-$199. They are available in Louisville Ky, so the must be available in other remote parts of the country.

I have seen the sx212 modem working on the sio port with a PD program called SX212 companion, which modifys your version of 1030 express to work with the sx212. SX212 companion also loads a handler that allows kermit65 or other term programs to use the sx212.

I have a Track ball demo programs in ACTION! and Basic.
(Scott @ ksuvm.bitnet) Send me e-mail or talk real-time over bitnet using the send command!

Now that I have posted a mod to convert the Sega light gun to work with the ATARI, there should be a mod allowing the Sega 3-d glasses to work with the 8-bits coming soon. Most of the mod would probably be in the form of software and maybe the construction of an adapter cord,(since sega moved some of the signals around the 9 pin din). Too Bad atari does not sell the Flight Sim II cart or the light gun separately, some one just might buy them.

Last but not least Here in Lousiville Rumours of atari losing money are floating around among the Computers dealer that are left around here. But we haven't had an Atari dealer for about 2 yrs.
(Neil Harris did you here this!)

It should work fine with MyDOS. It is just a matter of going through
the configuration stuff. If the docs that come with the drive are any
good at all, the configuration should be no problem.

I have actually seen that program around recently. It is not too bad.

Another program you might look around for is the Dot Magic aka Daisy Dot II
which is ShareWare and is quite nice. Works with Dot Matrix printers of all
kinds, incorporates Graphics, and different fonts. It has been found to work
with the XMM801 and Star SG10 printers as well. Various sizes of fonts are
capable as well. A bit slow sometimes but really nice. IS there an 8 bit
depository like the atari.st.binaries for this sort of thing?

> I would also like a package that I could select different fonts
> and sizes.

I believe that The Print Tool, by Marshall Abrams, will do most or all of what you want. The author has gone to some trouble to provide support for making up slides for presentations. The program is in the ANTIC Catalog. The author is on the net (abrams@mitre.arpa) and could probably tell you what capabilities the program has for your purpose.

Incidentally, The Print Tool is essentially "RUNOFF", the program DEC PDP-11 users know and love as a powerful text formatter for producing reports. It does automatic decimal section numbering, automatic compilation of index and table of contents, etc. Producing TV slides is just a tiny fraction of its capabilities.

I think you are looking at the depository. I posted Daisy Dot II here a
while ago. I have found one problem in using it: it is often a pain to put
all the formatting commands in the file after you format it. Anyone want to
tackle a macro package for TextPRO to support DDot II? It is something I
thought about a while ago, but I am busy with my Plato terminal emulator
project.

Speaking of which, when I finally get it completed, I will be releasing it
on a "if you like it, send money"-type deal. The final version should allow
for touch-screen emulation (depending on memory constraints) and screen dumps
to disk (definitly (sp?)). A separate program will dump it to disk. I should
have a good beta version done in a month or two, but I won't be able to post
it to the net 'cause this account dies at the end of the semester. If I don't
get a new account by this fall, I will have a new mail address on our Plato
system here (we are wired into BITNET) & you can contact me there. I know this
may sound like an ego trip, but I am too tired to go back and erase it all.

1176. disk drive problems

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-29 16:04:50 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <2803@bsu-cs.UUCP>
Source record: 116830

Hello all...

Some of you may remember my somewhat frantic postings last NOVEMBER on the subject of my "bugged" Percom AT-88 disk drive: the one that would simply suddenly cease being able to read chosen sectors from my disks?

Well, I got a lot of responses to that original query; some suggested cleaning the head (some saying "do it yourself," others saying "don't mess with it, take it to a proessional"), others suggested having the head alignment checked, etc. By all available evidence, Percom Data Corp. is long since out of business, and the two addresses that were posted for Percom service (both in the same area in or near Chantilly, VA) turned out to be the SAME company when I sent duplicate letters to both addresses. They didn't bother to answer any of my questions, just sent me a Xerox copy of their price sheet for new equipment, repairs, etc. Didn't say how long it would take, what shipment method they recommended, or anything else.

I was originally planning to summarize this in greater detail, a lot sooner, but hey, I'm a college student, and a BUSY one at that... I don't think I've even gotten around to PRINTING OUT the responses for posterity (although I DID READ them, lest you respondents think you wasted your time).

One good aspect of this lengthy interval is that I've had time to observe the problem more closely, and formulate another couple of questions for you experts of the Net.

1) The drive SPEED appears to be off: 293 RPM. This is either TOO SLOW, if the Percom AT88 is supposed to run at 300 RPM like "other standard" drives, or TOO FAST if it's supposed to run at ATARI standard 288 RPM. Does anyone know? Additionally, I opened the outer case to check on the possibility of adjusting this myself (using speed-check program and the strobe pattern printed on the flywheel), but couldn't find ANYTHING resembling a "potentiometer" (variable resistor) adjustment. Any info?

2) The drive seems to work all right when first turned on, but then to get worse as it warms up. This makes sense to me from an electrical standpoint, but I don't know enough about it to be sure, and the problem is STILL sporadic and hard to recreate.

3) I remember seeing something posted here by someone else, explaining a similar degeneration in the performance of his disk drive, which he eventually traced, as I recall, to a problem in the power supply. If that person, or anyone who remembers (or saved) his posting, is reading this, I'd appreciate a pointer to him, so that I could pick his brains as to whether I'm having the same problem or similar.

Thanks in advance,

Chris Chiesa

1177. 16K cartridge - How?

Newsgroup: comp.sys.atari.8bit
Date: 1988-04-29 17:42:37 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <2806@bsu-cs.UUCP>
Source record: 116831

I've recently been trying to learn about the innards of one of my game cartridges (CENTIPEDE, to be specific). I find that I can go into BUG/65, move the display list and display data "out of the way" of the Cartridge memory areas, then snap the cartridge into the slot and have its ROM suddenly appear in the appropriate address space.

Using this arrangement, and assuming for convenience that I plug CENTIPEDE into the LEFT cartridge slot on my 800, I find that 8K of address space switches from RAM to Cartridge ROM. I can then copy this 8K of data down into RAM, unplug CENTIPEDE, and copy the data back to its original addresses which are now RAM again. The same bytes are now in the same addresses as when CENTIPEDE was there "in person." So far, so good.

If I execute at the "cartridge run address," with CENTIPEDE plugged in, it works. I can play CENTIPEDE. But when I go through the above procedure, and try executing the SAME code in RAM, it DOESN'T work! I get a display of the title screen, and the "demo mode" makes a fair attempt at execution, but the P/M graphics are totally garbled, and you can't get beyond the title screen to try playing the game.

I have several theories about this phenomenon, which I'd like to bounce off you of the Net.

1) Centipede is a 16K cartridge and I'm just not getting all the code.

Support: opening the cartridge, there are TWO chips inside, as opposed to ONE chip inside Atari BASIC; Atari BASIC DOES work properly under the ROM-to-RAM copy scheme described above.

Questions:

How do I get at the other 8K ? Is there a "switch" address in the ROM that toggles in the second half "upon request"? Or does it appear in some other, hidden memory block that I haven't found yet?

2) Centipede is an 8K cartridge but detects RAM-vs-ROM execution and bungs up if you've moved it to RAM.

No real proof OR disproof of this one, except that "that's something I'd probably do if I were Atari."

There ARE a few places in the code where an LSR (logical shift right) is performed on memory addresses WITHIN the Cartridge ROM. I haven't been able to determine whether these operations are part of "detecting ROM vs RAM" or "swapping in a second 8K". I also haven't looked at the WHOLE 8K yet, of course; it's an ongoing effort and your responses here will be helpful in "pruning" paths of inquiry that are in the wrong direction.

Please post or e-mail anything you may know on this type of thing; the manuals are amazingly sparse. The only comment I've ever even SEEN about 16K cartridges was something to the effect that "...Atari designed a second slot into the 800 with the intent of marketing larger-than-8K programs as TWO cartridges, but then they discovered a way of putting 16K programs into ONE cartridge, ..."

This implies that I'm on the right track, but this is ALL the documentation there seems to be. Thanks in advance for any info you Netpeople can provide!

I believe I saw such a macro package for Text Pro on Compu$erve a few months
ago. I think it was only intended to 'help' format text for Daisy Dot though.
I believe it was in data library number 5.

I was on a BBS in New York last night and saw several messages that
indicates Flight Sim won't work with the new drives.

HAven't confirmed this as yet. So until I do, this is just a rumour.

Does anyone else know of this problem and if there is a fix? The consensus
on this bbs was that there was NO fix forthcoming.

Source record: 116835

I agree with wallman-george@yale-zoo.arpa (Natuerlich!) responding to Stan Lackey's suggestion to use the jump at VBI at the end of a display list to jump to an alternate display list. (This was to automatically display alternating screens meant for the left eye, then right eye, etc. to achieve a stereoscopic effect with a minimum of software coding). I tried it on a 400 and found that the address in the jump instruction is ignored, the computer continues to use the original display list and the display doesn't change. Perhaps as wallman-george@yale... points out, something has to be done to 'shut-off' shadowing of memory locations pointing to the display list. I haven't figured out how to do it though (or if it is even possible). Maybe it works on the XE machines.

> display doesn't change.
> Perhaps as wallman-george@yale... points out, something has to be done to
> 'shut-off' shadowing of memory locations pointing to the display list.

Well, you've got the basic idea: that the OS VBI routine is restoring the hardware Display-List pointer from shadow locations 560,561 (dec), AFTER the Antic JMP instruction tries to go somewhere else. You need to either SHUT OFF shadowing of 560,561 into hardware, OR update THOSE locations so that THEY ALSO point at the new Display List.

Shutting off shadowing may be as easy as setting the CRITIC flag, suppressing part of the VBI processing -- but I'm not absolutely sure that the shadowing you want to suppress, is part of the code getting suppressed, so that may not work. To be absolutely sure, you'd want to write your OWN VBI routine that took care of whatever OS operations you wanted still to happen, but DIDN'T shadow the Display List locations.

Updating the shadow locations on the fly could be done most easily in a short DLI (Display List Interrupt) routine; in the middle of display "A", the DLI kicks in and changes the shadow registers to point to display list "B". And vice versa. Note that the DLI needs to know which display list it is currently in; you need to maintain a flag, or switch, in memory. The advantage to THIS method is that the code is relatively short, you don't have to take up the burden of anything the OS normally handles for you, and you can turn the page-flipping DLI on and off by playing ONLY with the Display List.

Of course, in NEITHER application are you limited to TWO display lists, although if you're after STEREO that's all you really need.

The following information is directly from the ICD BBS. I don't know if it
answers all the questions, but it is a good start.

SpartaDOS X

Just what your 8-bit has been waiting for...a cartridge based DOS which
increases the power of your computer and includes an abundance of features
such as automatic Ultra Speed I/O with the Indus GT, US Doubler, and High Speed
on the new Atari XF551. SpartaDOS X is a fantastic new version of its disk
based cousin.

Even though SpartaDOS X is a 64K cartridge, it requires no memory from your
computer. You may piggyback another cartridge on top of the SpartaDOS X
cartridge and operate just as if you had booted from disk -- except much, much
faster. Here are just a few of the advanced features found in this cartridge
based DOS.

High Speed drive access with US Doubler, Atari XF551, and Indus GT
drives.
New improved menu program. Shows entire directory tree and performs
multi-file operations.
Supports up to 1 meg of internal memory as a RAMDISK.
The Lowest MEMLO of any DOS!
Powerful file loader supports relocatable files and symbol linking.
All new command processor includes parameter passing on batch files,
user definable prompt, and search file paths.
Commands now allow MS-DOS syntax!
The most commonly used commands are built right into the cartridge!
Atari 800 support with Axlon compatible upgrades.
Built in, all new formatter pops in with an XIO#254.

SpartaDOS X runs on an 800XL, 1200XL, 600XL (with expanded memory), 65XE, 130XE
800XE, the XE Game System, the old 800 with Axlon compatible RAM upgrade.

NOTE: SpartaDOS X will become available in June 1988. ($79.95 MSRP)

OK, you hackers out there, has anybody written a PostScript interpreter for the Atari 8-bitters? How about a TeX package and software to print .DVI files?

Probably this sort of technology requires too much memory and computing horsepower for the 8-bitters, but they continue to surprise me, so I thought I'd ask anyway! (I believe all of the above IS available for the ST.)

I'm looking for a volunteer to help maintain the software archives for
8-bitters. We've got a name for the archive, PROG-A8, and have a server
that can hold the data. Now all we need is a volunteer to actually do
the insertions of pieces into the library, and other misc maintainance.
You must, of course, have access to a host directly on the BITNET.
Replies to me or Abrams@Mitre-Bedford.ARPA.

Unfortunately, I doubt you'll see it soon. Most people wouldn't want to
wait 2-6 months for an image to be developed, and in 320x192 resolution.. :-)

The PS interpreter I have for Sun 3/50s takes 5 minutes to display a decent
sized graphics file.. :-(

To print DVI files requires you have access to fonts. Fonts require
megabytes and megabytes of disk storage. Plus lots and lots of numerical
computations. Unfortunately. :-(

Still like my 1980-edition 800 tho' !

Answers - yes and yes respectively. I don't see any reason to go
to the added expense of replacing existing equipment with something
practically identical, but if you can get a hold of the proper
handlers for the direct 8-bit hookup, it would be a good modem for
a 0-300 baud replacement.

>on the XE machines.

Nothing easier than that. Just circumvent the usual OS routine. As usual
I don't have my Atari sitting here "at work" but this should work (in
BASIC).

```
POKE 54286,0
POKE 546,PEEK(548)
POKE 547,PEEK(549)
POKE 54268,192
```

OK what I think this will do is preempt the immediate VBI by using
the deferred VBI that doesn't do the shadowing and usually does
nothing. 54286 is NMIEN that turns VBIs and DLIs on and off.

Watch out. Lots of stuff will not work anymore with shadowing disabled
such as 'comfortable typing' SETCOLOR commands etc. If you use
BASIC pure in the first place, you won't get very far. Better write a
little VBI that does the work.
DISCLAIMER: the statements were done w/o consulting either my indis-
pensable Mapping the Atari book, nor by trying it out on a computer.
But I am confident that above statements are true.

Keep your 850 and Avatex HC. The Avatex HC has all the S registers available
while the SX-212 has some missing. (Never were placed in, listed as RESERVED)
While the SX-212 looks smart, it's still not as smart as most other modems that people
use\have.

Now if you did'nt have the 850, i'd say get the SX-212 then find the P\D
program called " SX Companion " which will allow you to use the SX via the
SIO port at both 300 and 1200 Bps

>buying them.

Directly buying them: try Babbage's. Some dirt cheap software is there.
Unfortunately, they focus on Commodore (vomit), IBM, and Apple more than
the Atari 400, 800, et. al. At least this is the case in suburban Chicago.

Mail order: I don't know any right offhand. Sorry.

> I also heard that there is a catalog of game carts

Did you try Walden Books, B. Dalton Bookseller, Kroch's and Brentano's, or
Crown Books (Discount)??

I'm not even sure anymore if they sell just the magazine or just the
magazine/disk combination. I stopped buying Antic several years ago because
it was *too* rich for my blood.

I hope this helped you in some way.

Steve,

Yes, the SX212 is FULLY Hayes compatible. You can even use it with non-Atari computer equipment if you want to. If I were you, I'd keep the 850 and your modem-cable; you just unplug that Avatex, plug in the SX212, and do what you were doing before-- only BETTER! I'm running this combination of 850 and SX212, using the standard Atari R: handler and Kermit65, to type this very message. So it does work, and quite well at that.

Felix,

I tried to mail this response, but as usual, it bombed. Might be of
interest to others also, so I am posting it. Got to keep the activity
level here high enough to stay in existance anyway :-).

ANTIC is usually available in all the big Bookstores such as Crown, B. Dalton,
Waldenbooks and a lot of news stands that carry any of the computer magazines.
I don't know how available that makes them in Pittsburgh, but they are
readily available here in Chicago area.

For you information, here are a couple of sources that carry Atari computer
cartridges. Call them and they might be able to read you off the list of
what they have or send you a listing. Don't forget that the XE Game System
cartridges will work in the Atari 400 (except Flight Simulator) and they
are available at Toys R Us and other big toy stores.

American Techna-Vision
15338 Inverness St.
San Leandro, CA 94579
(415)-352-3787
[They have a lot of repair parts for the 8bit Atari's also]

Electronic One
P.O. Box 13428
Columbus, Ohio 43213
(614)-864-9994
[Their ad hasn't been for a couple of issues, but they had a long
list of cartridge software, so I'd call to see if they are still
in business]

Hope this helps...

My Centipede cartridge (CXL4020) is definitely an 8k cartridge.

>
>
> Questions:
>
> How do I get at the other 8K ? Is there a "switch" address in the ROM
> that toggles in the second half "upon request"? Or does it appear in
> some other, hidden memory block that I haven't found yet?
>
Standard 16k cartridges occupy memory from $8000 to $BFFF. There are two
ROM enable lines on the cartridge connector, one for the block $8000-$9FFF
and one for the block $A000-$BFFF. There are also separate select lines
for the two banks of ROM, and only enough address lines for 8k. All this
surely is a remnant from the design of the 800's memory.
See "Mapping the Atari", Appendix 14, or the schematics for your system,
for more detail.
Then there are the bank-switched cartridges. Basic-XE, for instance, crams
16k into an 8k address space. Switching is done by addressing locations
$D500-$D5FF. $Bxx addresses one block of ROM or RAM, $Axx addresses one of
three blocks of ROM or RAM. (I hope I got this right, haven't actually
had a chance to play with one).
Your cartridge definitely is not bank-switched.

>it's an ongoing effort and your responses here will be helpful in "pruning"
>paths of inquiry that are in the wrong direction.
>

I would guess these are data areas or tables of addresses.

>Chris Chiesa
>--

There are other, more innocent possibilities:

1. During initialization the OS sets up numerous pointers based on the size of RAM that it finds. Addresses $6A, $2E4-$2E6 come to mind, but there may be more. To keep everything away from the cartridge code you have to set up all of these just right, or someone might trash part or your RAM. The only way to be sure you are doing it right is to paw through the OS listings, and try to duplicate whatever is done there.

2. Some OS scrolling and screen clearing routines touch memory beyond the end of the screen area. Read what "Mapping the Atari" has to say about location $6A for more details. There might be some interaction with BUG/65 and its screen handling, too. You might experiment with setting $6A (and related cells) to a value lower than $A0. Also the Centipede cartridge might have routines which are doing similar sloppy things.

3. I would also be concerned about what happens to your system (and memory contents) when you plug and unplug a cartridge while the system is running. After all, you are disturbing everybody's address and data bus when you do that.

Happy hunting,

Hans

1202. Re: 16K cartridge - How?

Newsgroup: comp.sys.atari.8bit

Well, I can't say anything for certain since I don't know for *sure*
why Centipede isn't working when you move it to RAM, but I can say
for *sure* that a lot of cartridges were copy-protected to prevent
people from just dumping their code to disk and having copies being
distributed. A few years back when I was more into hacking on the
Atari, I decided to do just what you're doing - trying to get carts
put onto disk files. Some worked fine. Others didn't work at all, or
worked for a short time (ie - title screen or whatever) and then got
garbled. So I started disassembling the code. Lo and behold, some of
the carts had an interesting protection scheme - namely, they write
garbage bytes to random (or specific) addresses of the carts
residence ($A000-$C000?). If the cart is plugged in, there'll be
ROM there, so writing can do no harm there. If the program happens
to have been converted to RAM, well then it just gets trashed.
Of the 15 or so carts I eventually transferred to disk, about 7 or
8 had this type of protection. Of those, only 1 had the actual
"pokes" hidden in such a way that it didn't immediately jump out at
you when you disassembled the code. The solution is easy enough: just
disassemble the code and replace any code that writes to cart
locations with a NOP (decimal value 234 I think). Good luck.

Does the sx212 support error checking? I use my avatex and the 850 to
call school, and I get a lot of line noise. Or do I have to go to a
higher baud rate before the modem will support error checking? And the
problem is I have to give the 850 back to the person who let me borrow
it, that is why I was asking about the sx212.

Steve.

Hmm... I'd have sworn I'd seen two chips in there when I opened it. Maybe I'm thinking of something else. But BASIC and CENTIPEDE are the ONLY two carts I have. Don't have the CXLnnnn number here (I'm away from home at the moment) but that LOOKS right...

Whaddya mean a "remnant"? This IS an 800 I'm talking about here! :-)

> See "Mapping the Atari", Appendix 14, or the schematics for your system,
> for more detail.

I'd already looked at "Mapping the Atari," appendices and text; haven't looked at the schematic though, and I don't think it would tell me anything if I did: it's all a bunch of lines and gibberish to me... (This is why I got OUT of Electrical Engineering and into Computer Science... ;-))

> Then there are the bank-switched cartridges. Basic-XE, for instance, crams

> Your cartridge definitely is not bank-switched.

I don't understand what you just said! In fact, I'm having a devil of a time even explaining what it is I don't understand. Basically that didn't make much sense to me; could you clarify it? What memory address controls the bank-switching? $D500-$D5FF is a 256-byte range, neither a single "control register" nor an 8K block; I don't understand what appears there, under what conditions. What about "$Axx" and "$Bxx"? Is that a value that goes into some control register, affecting what data appears at bank-switched addresses? I'm confused!

> > 2) Centipede is an 8K cartridge but detects RAM-vs-ROM execution and bungs up
> > if you've moved it to RAM.
> >

Okay. I won't waste any more time on that concept.

> >There ARE a few places in the code where an LSR (logical shift right) is per-
> >formed on memory addresses WITHIN the Cartridge ROM...
>
> I would guess these are data areas or tables of addresses.

I suppose that could be, but I don't understand HOW. Doing an LSR on a ROM lo-
cation doesn't affect the contents of that memory address; the only non-ROM
data affected by an LSR, as I understand it, should be the Carry bit in the
condition-code register. But in this case, the LSRs (for of 'em) DON'T seem
to be followed by anything that USES the Carry bit. It's as inscrutable a piece
of code as I've ever seen! I thought maybe the specified ROM address was a
"switch" register under certain conditions...

> may be more. To keep everything away from the cartridge code you have to set
> up all of these just right, or someone might trash part or your RAM.

I don't understand how this would interfere. The first thing I tried, in fact
the thing that got me started on this, was a "CARTCOPY.BAS" program that simply
copied an 8K cartridge from either slot (I have an 800) to a disk file. It
worked fine on the Atari BASIC and Assembler/Editor cartridge, but bombed out
on Centipede. The program comments indicated that it worked "... only for 8K
carts...", which was what led me to think Centipede might be 16K, for one thing.
But the point is, as far as can be told, the SAME DATA in the SAME ADDRESSES
WORKS when it's running from the CARTRIDGE, and DOESN'T work when running from
a disk file (or direct-copied RAM). Does this, and your comment, imply that
I'm not really getting the SAME DATA to DISK as is in the cartridge? I find
that hard to believe, especially in light of the way other cartridges don't
exhibit the same behavior.

> The only
> way to be sure you are doing it right is to paw through the OS listings,
> and try to duplicate whatever is done there.

Gack. I've been through those damn things forward and backward for the past
five YEARS without figuring out what the heck goes on in there... I still don't
understand how the heck the WARMST and related flags work; it's still "magic"
to me and I find that incredibly frustrating.

On a related note, though: I've noticed that loading a binary file into RAM at
addresses which at other times are cartridge ROM, seems to make the machine un-
happy. I've seen innumerable programs which load, say, 7K of data into some-
where ELSE, then go to a lot of trouble to MOVE the data into, say $A000-...
I've experimented with altering these files to load directly at $A000 in the

first place, and often as not they bomb the machine. Why? Why? Why??

> 2. Some OS scrolling and screen clearing routines touch memory beyond
> the end of the screen area. Read what "Mapping the Atari" has to say

> Centipede cartridge might have routines which are doing similar sloppy
> things.

No, I took care of that first thing. Moved the display list, screen memory etc. well below cartridge area, and then set $6A just above my "new" memory area. And then didn't EXECUTE the ROM, just MOVED the data hither and yon...

> 3. I would also be concerned about what happens to your system (and memory
> contents) when you plug and unplug a cartridge while the system is running.
> After all, you are disturbing everybody's address and data bus when you
> do that.

That's what I always thought. But that aforementioned "CARTCOPY.BAS" program used this technique and simply said "if the machine locks up, reboot and try again." It seems to be a matter of getting the cartridge in STRAIGHT, FAST, and ALL THE WAY. Any "tilting" of the cart so that one end of the bus engages before the other, sends the machine off into la-la land. But the computer doesn't seem any the worse... What exactly am I risking, besides locking up the current "session"? Is there a better method?

Source record: 116860

Christopher,

Regarding your Centipede experiment, I can give you some assistance. First of all, there's a way to get around the RAM-vs-ROM protection schema: you built yourself a 'blank cartridge'; a cartridge that grounds the 'read-only' pin of the cartridge port. You see, when the 'read-only' pin is ground, the Atari won't write to its RAM where the cartridge resides ($A000-$BFFF) even though it is RAM. If you don't know where the 'read-only' pins are, let me know. I will look them up for you. There are two 'read-only' pins in the left cartridge port. One is for $A000-BFFF, and another for $8000-$9FFF.

About 16K Cartridges, they come in different sizes and shapes. For example, one of the well known 16K cartridges, "Action!", has a 4K block of codes reside in the Atari at all time while 3 other 4K blocks of codes are being switched on one at a time. They also called 'bank selecting' cartridge. Although they claim to be 'un-copyable', I have seen some hackers managed it by modifing a 256K 800XL to simulate the bank switching.

Although I don't do any Atari anymore, I still remember a lot from the old days. If you have any more questions, please don't hesitate to ask.

If anyone DOES come up with tech-specs for the Sega 3D glasses (voltages, currents, pulse form requirements etc.), and if anyone else knows where to get them, I'd be happy to throw $60 into 'em. I've been a stereo nut for years, so this is a worthwhile expenditure.

1210. Atari News

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-07 15:37:50 UTC
From: kimes@ihlpe.ATT.COM
Message-ID: <2918@ihlpe.ATT.COM>
Source record: 116864
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

I found the following article in the latest issue of the electronic atari newspaper called Zmagazine. It is attributed to the Computer Shopper though, so credit should go there. Since the Zmagazine is carried on many BBS's and CompuServe, it is public domain, but I am giving proper credit.

BULLETIN BULLETIN BULLETIN BULLETIN BULLETIN BULLETIN

835 27-APR 21:27 General Information
Atarians Rejoice (?)
From: DFSCOTT
To: ALL

This is a Computer Shopper exclusive story.

Atari Corp. is undergoing another corporate restructuring, but this time more massive than before. A division company, to be known as Atari Computers, is being formed. Charles Babbitt has been named Atari Computers President, and Anthony Gould his Vice President for Sales. Although still under the umbrella leadership of the Tramiels, it appears at this time that a semi-autonomous company in the manner of Amiga Corp. is being spun off. In an exclusive interview, Atari chief spokesman Neil Harris told this reporter that Babbitt has been given two months to form a new corporate strategy for Atari Computers. During that period of time, says Harris, Corporate leadership has ordered no one at Atari Computers to speak with the press. Nonetheless, Babbitt was cornered into releasing general information to Computer + Software News about a special packaging arrangement of the Mega 4, perhaps for sales to Value-Added Resellers.

It apparently has yet to be decided what role current Atari Corp. management will play in leading the new Computers division. More details as they become available.

END OF ARTICLE

Since it is not dated April 1, I assume it is for real. If so, it may be the answer to all those that have been Atari bashing lately. I view it as a positive step for Atari and one that could raise their credibility IF they can bring more products to market. I have also read that because of chip problems, etc., Atari will be out of virtually all products by the end of the year. No amount of reorganization will help if you don't have a product to sell.

1211. modems and the 1200xl

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-07 18:18:00 UTC
From: PHR140@URIMVS.BITNET
Message-ID: <8805072106.AA22690@ucbvax.Berkeley.EDU>
Source record: 116865

One thing I found out when I first started using an Avatex
1200 modem with an R-verter interface on my 1200xl was that the
interface was not getting enough power. I remembered that there
is a current limitting resistor on the +5 volt line of the sio
bus. This is resistor R63. If you put a jumper across this
resistor, you will be able to use an r-verter or an p:r: connection
with the 1200xl. Also, if you want to get at the croma video
signal (to feed monitors that have separate croma and luma inputs)
you can connect a 0.01 uf capacitor to the junction of R184 and
C119. Attach the other end the the free pin of the video jack.
Using this configuration gives a much better picture on the
commodore (ack!) monitors, and other monitors that support this
type of vide input.

1212. "Atari Computers" , was Re: Atari News

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-07 23:50:27 UTC
From: c60b-at@buddy.Berkeley.EDU
Message-ID: <3179@pasteur.Berkeley.Edu>
Source record: 116866
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

That Atari Corp. is spinning off a Computers division should be very good; as long as they get money from Corp. At last, there will be an organization that will deal with Computers. Not games, calculators, or suits against chipmakers. Maybe there's the slightest chance that Atari will start acting like a real computer company.

Here is my wish list:

1. More updates to GEM. It's the ST's _OS_ for chrissakes, everyone :-) has to use it so it better get fixed and enhanced.
2. More support for developers. Face it, Atari has no respect so it might as well be nice to the people who can keep the machines alive.
3. Buy an IC factory (unless this has already been done). and get the blitters out. THEN get the roms for the new GEM out. And on the latest TOS; send it to stores to be distributed by them. Have the retailers copy the disks for them. It would get customers for the retailers and get the revisions out.
4. For the 8-bitters. The next batch of OS roms should have the Newell Fastchip routines built in. Buy rights to put out the Newell code and maybe Newell will make a profit. I see his Fastchip going for $15 every-where. I don't see how he can be making anything, considering the size of the 8-bit market.
5. Again, 8-bitters. Sell Flight Simulator 2 on cart, maybe someone will buy a FSII that does no disk access! Indicate on the XEGS packs which machines a given cart will run on. (and accurately)
6. More user support and service.
7. Give the computers better names (from now on, it's too late for the st and xe). The computer is be an extension of the HUMAN mind. A computer should have a short (4 syllables or less) name that has a minimum of "whiny" sounds (ee,aye).
Here are some bad names and why I think I hate them:
ecks-ee too whiny, and it sounds like a sports car
ess-tee ditto
a-mee-ga whiny. reminds me of amoeba and Velveeta.
ps/2 says nothing, in other words, very IBM personality wise
Microsoft sheesh. not only is it small, it's soft. feminists may protest, but a weak phallic association turns everyone off. Note: I am not advocating "LargeHard" as an alternative:-> Imposing names are also bad.

Generally, these names do not sound good in conversation.
These do:
Macintosh canadian/scotch sounding. not wimpy (the machine may be though)

Dr. Halo luminescent sounding.
Dell (as in Dell computers) just good sounding
Grid one of the best Hi-teck sounding names.
etc.
And pertaining to the topic is the choice of numbers, i.e. 1040ST, Apple2.
obviously, XF551 is vastly worse than 1040 or 520. But 1040 is not as
1 or 2. I know very little about this, but I guess that the "best" numbers:
have no suffix like hundres or billion, can be said with few words as in
ten-forty or fifty-five, or have repetitive digits if they are long as in
six-two-six three-twenty-three, or are single digits. There should also
not be too may different models for one name. Imagine mega 2,4,6,8,10,11,14.

I realize that some people believe the name of a product has little to do
with it's desirability, and back when micros were bought by hobbyists this
was true, but now, we are dealing with "normal" people who don't have a
hacker's appreciation for programmability, instruction sets, and power
requirements. It's going to be a mass market, and that demands mass market
measures. Now, computer companies must hire logo, case, and graphics
designers as well as engineers. This is inevitable, even for a cost-cutting
outfit like Atari. Promotion and design are as much a part of business
as is manufaturing.
I am not advocating that Atari change the name of the ST and XE, they
already have name recognition, but they should not name the next product
the TT or EST or A?AQ (or promiseLAN, that's plain stupid). How about
names like: The Roadway, the Michael, the David (as in D&Goliath for all
the Bible nuts out there :-), the Stone (for go players), the Audrey.

1214. This and that

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-09 19:48:22 UTC
From: AXDFM@ALASKA.BITNET
Message-ID: <8805091904.AA29789@ucbvax.Berkeley.EDU>
Source record: 116868

Well, some general comments that I kept meaning to make, but never took
the time. Here goes a little of everything:

SX212: It is a real champ of a modem. I have had one perform flawlessly
for four months. I had bought from the last modem from the first shipment
of SX212 to our local dealer, and it was not a champ. Really noisy....
A friend of mine had also bought a SX212 and had the same problem with noise.
I was pretty mad, and I took it back. The dealer exchanged the modem, and
the wait was worth it. I think that I just had a fluke, but my friend did
too, so you may want to watch out for early 212's. I wouldn't let that
stop anyone from buying one, because they are really awesome modems, and
the one I have now is doing pretty good....

XEP80: I have one of these suckers, but all it does is collect dust.
What software is out there that works with the thing? I have something
like Amodem 4.2 that works in 80 column, but Xmodem only works at 300bps,
so it is not that hot of term program, esp. compared to Express. Does anyone
know if a VT100 emulator exsists for the xep80? Does anyone know if any
software period exsists for the xep80? Where can I get a list of it? Where
is a BBS with software for it?

Ultima V: Does anyone know the latest on this game? I want my Ultima!!!!

APAC: What is the general opinion of Analog's APAC (Any Point, Any Color)
program? It works okay, but I tried some stuff with it in BASIC, and it
was really slow. I downloaded it off of GEnie, so I don't have the magazine.
Does the source code appear in the mag? I am trying to write some mac/65
macros for it, but I lack some vital details, and I must be missing something
here.... Any help on the subject is appreciated....

MAC/65: Does anyone want to share some macros out there? I am a junkie
when it comes to this sort of thing, and I don't have alot of mac/65 macros
in my library. Specifically, I would like to see a mac/65 macro for processing
SpartaDOS parameters. Anyone know where some are?

I am sure that I have not got everything I meant to, so I'll probably
be back with another long one soon.... Have a nice fun day!

>the answer to all those that have been Atari bashing lately.

Sounds interesting, but if all of the Computer business is one division what
does everyone else do? Video games? I'm thinking this would make the org
chart something like ...

```
Tramiel Bros...
|
+--------------------+-----------------------+
Babbitt ???????
Atari Computers VideoGames (2600 et al)
| |
+-------+--------+
Roy Neil ???
(SW) (Mktg) (HW)
```

Wonder if they can pull it off. They definitely need to restructure it in
some way. There is no way they can sell a UNIX box (aka '030) without a
fully staffed customer support division...

1218. Comdex report

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-12 15:39:34 UTC
From: conklin@eecae.UUCP
Message-ID: <8254@eecae.UUCP>
Source record: 116872

Well after 2 days at Comdex, we got our work done early and came home so I thought you might be interested at what was news.

Atari was there, on the floor with a relatively large booth. This is a very serious attempt at marketing because even a small 10 x 10 booth will cost a company upwards of $40,000 to put up, and Atari's booth was about 40 x 40.

The Atari booth had Mega ST's everywhere. Almost every display was a Mega, except for an occasional 1040. After searching the entire booth, I finally asked and found that Atari did not have a _single_ 8 bit on display.

On the other hand, Atari did have a '286 AT compatible on display, and a couple of the Atai Laserprinters. I didn't notice them in operation but I was very busy at the time.

Neil Harris was there, and so I asked about his presence on the net. His presence or lack of is simply a matter of time. He logs on to things about 4 (?) times a week these days. He did mention that several people in engineering log on, so ifyou guys are out there, please speak up.

As for products at the show? I wasn't really looking. I just kept thinking about the thousands of people back home with 8bits. But we've gotten to the point where millions count.

One thing that Neil Harris did mention that I thought was interesting. 8 bits still account for a meaningful amount of sales, largely because they are being sold to (suprise!) Poland now. I think something like 100,000 units sold in Poland or such. Interesting.

Such was excitement. Sorry I don't have more, but Comdex is a big show and the few minutes I spent at the Atari booth was probably the most I spent at any single vendor.

As far as I know, Atari has never displayed or tried to push the 8bit machines at COMDEX. This simply is not the right show for it. On the other hand, they should have a pretty good push of the 8bit machines, especially is the guise of the XE Game Machine, next month at the Summer Consumer Electronic Show here in Chicago. I will be looking at Atari and all the third party software houses to see what, if any, bright spots I can find. ANTIC usually has reports on Compuserve that someone posts here. I will have my own report, although much abbreviated from what you can find there.

Message-ID: <8805141943.AA14400@mitre-bedford.ARPA>
Source record: 116876

The general convention, throughout the internet mailing lists, so far as I know, is that to ask for assistance with subscribing, unsubscribing, or fixing distribution problems for list

info-xxx@yyy

you send your request to

info-xxx-request@yyy.

Originally, info-atari was one list (for 8-bit users). Then the ST came along and it was one list for both 8-bit and ST news. Then they split it into info-atari8 and info-atari16, but did not split the info-atari-request address.

Send your request to

info-atari-request@score.stanford.edu

and you should get a reasonably prompt response to your request.

-John Sangster / jhs@mitre-bedford.arpa

P.S. *** PLEASE *** do the net the favor of REMEMBERING this address if you should decide to unsubscribe at some future date. DO NOT ask all of us readers of the postings to unsubscribe you, as most of us can do that no more easily than you yourself can.

Date: 1988-05-16 03:31:09 UTC
From: rich@lakesys.UUCP
Message-ID: <670@lakesys.UUCP>
Source record: 116879

[]

I have a question for other users of the net that have been
servicing and or have run into this problem.

I have a 130 XE machine, that will not allow one to do
anything except watch the RAM test in the self help
diag's text. It goes there right off. Once in a while one
can press RESET and get the machine to Basic, but after
hitting Return, major Lock-up.

Have tried the OS chip, wish another, and even my Omni view,
along with the Antic, the Salley and MMU (6161) all to no
avail. These seemed to be the place to start, but all yeild
the same problem. I was going to try the PIA chip, but think that
this would yeild the same, and really don't like de-soldering
40 pin chips. I can think of more pleasent things to do ;^)

Any help would be appreciated, as this one has me scratching
my head.

BTW. All is the same EVEN with the Keyboard not connected

rich.....

The truth is... I don't know....

When OSS was owned by OSS, the runtime package WAS NOT public domain.
You had to buy the package directly from OSS. But now that OSS is owned by
ICD... I don't know what their policy is...

My advice is... until you hear different (from a reliable source), consider
the runtime package copyrighted. And don't repost it anywhere.

Have you considered/checked the possibility that you have a bad 6502? I've seen that happen, although usually the thing just doesn't run, period. Could be just something subtle in that the reset line is getting tweaked when you don't want it to, in combination with something being wrong in the part of the CPU that automatically starts at such-and-such location in memory on powerup.

Just a thought...

1229. 2600 games on the 8bit?

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-17 07:55:00 UTC
From: rzimbins@umn-d-ub.D.UMN.EDU
Message-ID: <330@umn-d-ub.D.UMN.EDU>
Source record: 116883

Is it possible to convert an Atari 2600 game cartidge to work on an 8bit machine (specifically an 800)? I've tried taking apart the 2600 cartridge, removing the IC, and reseating it inside the 8bit cartridge (Space Invaders with its IC removed).
This doesn't work, but it feels like it ALMOST works. For a fraction of a second after I turn on my computer, I can see the playfield of the 2600 game, then there is nothing but a
dull green screen to look at.
The game unit and the 8bit computers are the same internally, aren't they? If so, it should follow that a chip designed to work with the game should also work with the computers, right?
If I'm way off base, please tell me why. If I'm just a little off base, tell me about that too. Heck, just tell me what you know.

-Bob Zimbinski

1230. compatibility

Newsgroup: comp.sys.atari.8bit

From: lackey@Alliant.COM
Message-ID: <1819@alliant.Alliant.COM>
Source record: 116884

Well, I finally decided to get the new XF551 disk drive, and yes, only
DOS 2.5 came with it. I read on the net that Spartados supports the
new features, so I dug my copy out of the pile and tried it. It really
does use the DS/DD capability. However, to my horror, I found that
the Atari assembler does not seem to run under it. I tried assembling
my homemade text editor (which is rather large), and found that it
seemed to load OK, but hangs up while reading one of the source files.
Is there any fix? If the fix is getting mac65 (is that what it is called?),
where do I get it?

Also - I noticed that people have been talking about putting cartridges
on disk. Can this be done without hacking the hardware? I would love
to get rid of those stupid cartridges. Even if it is just the ones
that don't overwrite themselves.
Thanks. -Stan

Steve Schimmrich writes...
> I would like to know if the RTL package for action is in the public domain?

As I understand it, OSS sold a package called the Runtime Library which was
a commercial product, not a PD one.

However, an enterprising soul on the net posted an "alternative RTL package"
awhile back. This was his own creation, and consisted of code to help you
extract code from the cartridge to a disk. He was careful to make sure that
the only thing he helped you get was the runtime library, which would not be
useful unless you had the cartridge itself or some compiled code that could
call the runtime library. If you own the cartridge, you are entitled to
copy it for your own use. If you want to make standalone programs that
use library routines that are in your own cartridge, you certainly have
the right to do that and put them on a disk. If you start selling those
programs, you may run into a gray area of the sort that makes lawyers wealthy.
If you merely share them with friends, I doubt that anyone will care.

> I was looking through my disks, and I found the rtl for action, but
> it is in superboot format. I dont have the program to convert it back to
> usable format. Does anyone out there ahave superboot? If so, could you
> encode it and send it my way??? I would be eternally grateful. Thanx.

> Steven H Schimmrich Dep. Of Geology SUNY at Albany

I don't have superboot (would like to find out what it is and get a copy),
but I do have the Poor Man's Runtime Library Package that was posted
awhile ago. Since I am sure that distribution of it to the net is authorized
by its author, I'll send you a copy (immediately if it is online here,
otherwise a few days). What you do with it after that is up to you.

Since the PIA is the chip that selects the self-test ROM, I would check the PIA first. Look at the logic line from the pin (I think it is Bit 7, the Most Significant Bit (MSB)) to see if it is asking for the diagnostic ROM (I think that would be a LOW output instead of +5 volts). Also check the logic chips that this bit controls. One of them may be burned out, causing it to command the diagnostic ROM into action even if the PIA is not telling it to. I suspect you will find the problem to be either a bad PIA or a bad gate driving the ROM chip select line.

> Have tried the OS chip, wish another, and even my Omni view,

> this would yeild the same, and really don't like de-soldering
> 40 pin chips. I can think of more pleasent things to do ;^)
Given the symptoms, the circuitry from the PIA to the O/S ROM is the probable location of the problem. Save all those parts you changed, 'cause they are probably perfectly good. Since you changed the MMU, I suspect it is, after all, a bad PIA chip. The only other thing I can think of is a short across the lines from the connector where the keyboard plugs in. Hah, that's eliminated by the fact that both OMNIVIEW and the Atari chip come up the same way. Since they react oppositely to the OPTION key, it can't be just a short that makes it look as if the OPTION key is being held down.

> Any help would be appreciated, as this one has me scratching
> my head.
It would of course help if you had a 130XE schematic diagram and a 'scope or at least a VOM (Volt-Ohm-Milliameter). But the more I think about it, the more I think it is probably a bad PIA. Either that or a fault in the wiring to the PIA, like a solder splash that shorts a pin to ground.

Good luck.

As I understand it, the 2600 has a completely different microprocessor
than the computers (I don't know what it has). While I have not heard that
the code cannot be converted, I tend to doubt that it can be done easily.

1234. Action! PD runtime pack

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-17 17:08:46 UTC
From: curzon@kaoa01.dec.com
Message-ID: <8805171708.AA00804@decwrl.dec.com>
Source record: 116888

There are 2 runtime packages (at least) for Action! The one that
was sold by OSS (and now presumably by ICD Inc) is the original by Clint
Parker. It is not PD. The other one I did a quick review of last year:

The other (PD) package is by Jeff Reister (sp?) of Mount Vernon,
Washington. It includes an adaptation of the ST Reversi game published
by Analog, and a font editor, along with their source codes, and the
assembler sources for the runtime package code.

The actual runtime package is contained in one relatively short file
(RUNTIME.ACT). It seems to be quite a bit more compact than the OSS
runtime package. There is also a program RTSCAN.COM (with sources) that
scans 1 or more source code files, and compiles a list of each of the
RUNTIME symbols that will be required. The list can be output to any
device. It lists symbols in the same order as they appear in the
RUNTIME.ACT file, and the number of calls made to each. Then it is
simple to load a copy of RUNTIME.ACT into the editor, and kill all the
unused routines/variables.

[There has since been posted to GEnie a program like RTSCAN,
except it actual creates the "minimum size" RUNTIME.ACT file, with only
the routines required by your sources. Any body tried that one?]

In all, this package makes less demand on your symbol table capacity
than the OSS package (fewer symbols). And, RTSCAN makes it easy to
include only the direct and indirect routines needed, to make your
runable binary file as small as possible, and minimize symbol table
demands.

If however you encounter symbol table capacity problems in
compiling a very large program, this package does not include a routine
to increase symbol table space (like BIGST.ACT distributed with the OSS
package), nor does it have documentation on exactly what system
variables need to be changed.

However, BIGST.ACT was released to the world by Clint Parker's BBS,
as copyright but to be freely distributed, so that could be used in
conjunction with this PD runtime package.

The package comes with a notice that although this runtime package
is PD, Action! programs can still not be sold for profit unless cleared
with OSS Inc. [PROBABLY ICD INC - NOW]

It is a very fine package, and a definite improvement over the OSS
package in ease of use-- no bugs found yet.

[I have since used the PD runtime package on a couple of small programs--
it works great...]

If I recall correctly, the 2600 uses a 6507 mpu and the 800 and co. use a 6502 mpu. So it shouldn't work. There are also differences in the sprite (player/missile) mechanisms. I suspect that there are certain similarities in both machines -- that they are close enough that a hardware device could be made to run both machines using common graphics chips. But They are different enough so the carts are not interchangable now and will not be in the forseeable future.
The _5200_ is the machine that is a 800 in disguise. 5200 games are portable to the 800 if some mods are made to the cart; of course, some code changes will have to be made to compensate for the joysticks. There was a cart mod article in an old ANALOG.

>to run both machines using common graphics chips. But They are different enough
>so the carts are not interchangable now and will not be in the forseeable
>future.

This is correct. These two machines are VERY, VERY different machines.
The games are quite totally non-portable (I am not sure why one would want
to port a 2600 game to a 400/800 anyhow, but that is one's own perogative :-)

>The _5200_ is the machine that is a 800 in disguise. 5200 games are portable to
>the 800 if some mods are made to the cart; of course, some code changes will
>have to be made to compensate for the joysticks. There was a cart mod article
>in an old ANALOG.

This is partially true. I guess that although the 5200 used the 6502 and
the Antic/PIA/Pokey chip set, Atari, Inc., in its infinite wisdom, brain-
damaged the 5200 enough to make it non-compatible with the home computers.
It is possible to transfer the 5200 games to the 400/800, but you have to
make software mods once you get the object file to the 400/800 since the
5200 uses those evil-joysticks-from-hell (that are two potentiometers.)
All of which seems much more trouble than it is worth, since there aren't
any 5200 games I can think of that didn't come from the 400/800 in the
first place.

One bit of trivia: the 6507, the CPU in the 2600, is also used in the
wonderful Atari disk drives! Yes, you too can build the 2600 emulator
for your Atari 1050...

As long as we are discussing game machines, does anyone know the technical poop about the 7800, the evil-black-sheep of the Atari Game machine line? Now some of the games I saw for this little gem were kinda nice. Also, does anyone know what kind of CPU that Sega or Nintendo use in their game machines (I assume proprietary...)

The way I heard it, the designer of the 2600 and 8bit video chips
were the same person. However, I also know that they are very different
machines. The 2600 CPU is a 6507 I think. I might have the number wrong
but it is essentially a scaled down version of the 6502 in the 8bit. It
only addresses 8K of memory, it's missing some interupts, etc. The 2600 also
has only 256 BYTES of RAM. There is no stack, so no subroutines are
allowed. There is also no video screen memory. The program must constantly
draw the screen and do its work during the Vblank period. The video chip is
called the TIA, but I have no documentation on how to use it.

Of course, this is quite unlike the 8bit with its wonderful abilities.
Therefore, it is not possible to move the ROMS between the machines.
(Then again, most if not all games on the 2600 are also made for the 8bit,
and they probably play a lot better on the 8bit. So why do you want to
run 2600 games on the 8bit in the first place?)

I happened to have a Sega machine in front of me, so I checked it's stuff.
It doesn't use a 68000, but a plain old Z80. (I had to take it apart to find
that out, but what the heck...(-:))
Other misc stuff:
128k ROM
64K RAM
128K video RAM
64 Colors
256x192 screen resolution
Horizontal,Vertical,Diagonal and Partial scrolling
3 four octave sound generators, 1 white noise generator
Maximum of 256 sprites

Nobody probably cares, but it's here in case you do....

This sounds like the problem I had with the Atari Macro Assembler (AMAC).
The disk keeps on spinning and seeking but nothing seems to happen...

|>Is there any fix?

Good question. Not that I could find. I think AMAC does some funny things
with I/O, specifically with a part of the IOCB that you are not supposed
to depend on (but it does). That's the reason for the problem.

|>If the fix is getting mac65 (is that what it is called?), where do I get it?

I have no idea anymore, but I know it permanently solved my problems, and it
was ten times faster. Granted, it is a bit obscure in a sense, but is
much more flexible (and has less bugs) than AMAC. Yes, AMAC has some really
bad bugs...

|>Thanks. -Stan

Sorry to only be able to provide this small amount of information, but I
hope it helps. Surely the same outfits that carry the Action! cartridge
will carry the MAC-65 cart and toolkit. Take a look in some Atari magazines.

>The XEGS has a Keyboard.!.!.

Yes. Too bad that Atari isn't doing any real support of this 65XE-which-is-a-800XL-in-a-funny-pastel-box. I for one would like to see them release the Flight Sim II cartridge for retail sale alone - even though it can't run on my vintage 1984 Atari 800, I'd buy a used 800XL for a game like that :-)

8bits are/were great. I'd be interested to see just how many Atari 400/800/XL/XE computers are gathering dust versus similar Commodore Vic/64/128 equipment (but that is another flame war... double :-)

Are you sure of this? I have seen the display on this machine and it looks much more dense. Perhaps the number of colors fakes one's eyes out, but this resolution is about the same as an Apple II--and those graphics are not arcade standard by anyone's definition.

Fixing small computers 101: (also applies to any other electronic equipment): Check the power supply. Make sure it puts out 5 volts and not much ripple. A scope is great for this, but a VOM will do. Actually this one does not sound like a power supply problem, but you never can tell for sure. And you always feel like kicking yourself when you discover, after much searching, that the solution was that simple.

When doing a coldstart, one of the first things the XL/XE OS does is a quick memory test. If that fails, it dumps you into the memory diagnostics, and it sounds just like that is what is happening to you. The fact that you get that far indicates that, in all likelyhood, the cpu, antic, gtia, parts of the pia, and the rom are all working. The RAM must be working at least somewhat, since the memory test must use it for scratch storage, screen, etc.

You did not indicate if the memory test seemed to be running, and how it thought that the RAM and ROM areas checked out. If you see some failures there, you should have some idea of what is broken. From the symptoms I strongly suspect that your problem is bad RAM.

Assuming that RAM is your problem, the next step is to identify the bad IC. Unfortunately the diagnostics go to much detail identifying the 1k region containing the error, but neglect to identify the bit. If your display is somewhat garbeled, the pattern may help to identify the bad bit. If your memories are socketed, swap away (you have a set of spares right there).

If your memories are soldered in, here is a trick I once used to fix just such a beast: take 3 memory chips, and bend their legs inward slightly, so that you can stack them on top of each other, and have them hold together tightly. Put this stack on top of a memory chip, and see if the problem goes away. If not, move it to the next one, and so on. Be sure to remove power whenever you are moving the chips, be careful not to short anything, and all usual precautions about handling static-sensitive components apply here, too.

When I did this, it turned out that two memories were enough to "outvote" the bad one, but one was not enough. I wold use three in case your error is more persistent.

I hope this helps!

Apparently I did not describe things real well on my last try, so here we go
again:
> Hmm... I'd have sworn I'd seen two chips in there when I opened it. Maybe I'm
Yes, there are two chips, but they are both 4k ROMs. Maybe these were cheaper
than the 8k variety at the time, or maybe one half contains subroutines
common to several games. The key thing is that they both are selected by the
S5 signal, which indicates the address range $A000-$BFFF. 16k cartridges
(with a flat 16k address space) will also use the RD4 and S4 signals, and
bank switched cartridges will use the CCTL signal. The Centipede cartridge
does not even have contacts in these locations. (See 'Mapping the Atari',
Appendix 14, for the pinout of the cartridge connector.
>
>
> Whaddya mean a "remnant"? This IS an 800 I'm talking about here! :-)
Sorry, I did not mean to offend you. But when you look at this from the point
of view of an XL or XE, this addressing scheme might seem strange.
>
> I don't understand what you just said! In fact, I'm having a devil of a time

> ter" nor an 8K block; I don't understand what appears there, under what condi-
> tions. What about "$Axx" and "$Bxx"? Is that a value that goes into some con-
> trol register, affecting what data appears at bank-switched addresses? I'm
> confused!
>
The i/o area address space $D500-$D5FF is decoded in the Atari, and the
result is fed to the cartridge as the CCTL line. This apparently was meant
for such applications as bank switching, and for cartridges with i/o devices.
After that it is up to the cartridge what to do with it.
The scheme I described is used by the OSS cartridges (Basic XL and XE,
Mac/65, and maybe Action, too). In the more common approach you would
store a value xx in a control register to accomplish a certain action.
In this scheme, instead, you reference location $D5xx.
This probably simplified hardware design.
So, for instance, a reference to $D500 selects bank 0, $D501 selects bank
1, and so on. Since these may be store instruction, this can be done without
affecting registers, which may simplify programming.
Where I referred to $Axx and $Bxx, that should have been $Axxx and $Bxxx,
to indicate that these cartridges treat the two halves of their address
space separately.
```

> > I would guess these are data areas or tables of addresses.
>
> I suppose that could be, but I don't understand HOW. Doing an LSR on a ROM lo-
> cation doesn't affect the contents of that memory address; the only non-ROM
What I suggestes was that these areas are not really code, but data used for
displays or whatever. After all, if you disassemble arbitrary data you some-
times get what looks like real instruction sequences. On the other hand,
if these LSR instructions are in the middle of what appears to be legitimate
code, then I was probably wrong, and this is some form of copy-protection.
You might try replacing these instructions with SEC or CLC, as appropriate.

> exhibit the same behavior.
>
You are probably right on this one, but let me explain my point. When you
boot without cartridge, the OS sets up numerous pointers to reflect a
memory size of 48k. When you boot with a cartridge, those pointers are set
up for a memory size of 40k. When you boot without cartridge, and then want
to run the equivalent of a cartridge, you have to change those pointers. My
point was that if you do not make all the changes needed, then some
cartridges may run, and others may not, depending on which pieces of infor-
mation they use. And of various pieces of code that I have looked at, I have
not seen one yet that set all of these things correctly.

I can't think of any reason why that should be so, but have made the same
observation at times. Never had the time to chase it down, though.
>
> doesn't seem any the worse... What exactly am I risking, besides locking up

> the current "session"? Is there a better method?
Apparently lockups are all you are risking. If you are going to do a lot of this, a switch in the S5 line would make the cartridge appear and disappear, while keeping the memory occupied at all times. You could add that either in the cartridge or in your 800.

please don't panic!!

I'm just wondering if there was an XE virus going around. i own
an ST and 3 8-bits (two 400s (one 48K) and a 600) and was wondering
this because i see so much about the ST virus and nothing of an 8 bit
one. i've never seen a "virus killer" program for the 8 bitters
either.

thanks in advance for any info! (hopefully positive)

I have never seen a virus for the Atari 8-bits. I have thought about it
before, and I think it would be fairly difficult to implement. One obstacle is
the fact that there are so many DOS's and disk formats. A virus might be able
to hide in sector 720 on a DOS 2.0s disk, but the same scheme would probably
not work on a DOS 2.5 disk and would certainly not work with SpartaDOS, MyDOS,
and all the other odd DOS's out there. Another obstacle is the noisy I/O. Even
if a virus is created, the Noisy I/O allows an experienced user to know
what is going. For example, if you open a file for read and hear the low
clicks, you know something odd is going on. Creating an 8 bit virus would be an
interesting project. Maybe someone could make a benign one that does something
like print "Bang! You're dead!" after it has been copied X times.

|>
|>
|>Bitnet: Phr140@urimvs

There isn't a SIMPLE patch available. The problem is that US doubler works
by modifying the serial I/O (SIO) port speed. When this happens in Sparta,
the normal serial port routines are swapped with a modified set which operate
at the faster speed. The speed index is obtained by querying the drive with
a special disk operation code. If you are lucky, someone may have made a
patch which works with other DOS's which handle the US doubler's ultra-speed.

The next question is why you aren't using SpartaDOS? I've used all types
of DOSs, but Sparta seems to be the best one available. I guess that too is
a matter of opinion, but I think that you might be better just switching
to Sparta.

1254. Re: Atari 8-bit virus??

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-22 21:36:05 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <3171@bsu-cs.UUCP>
Source record: 116758

I'd be surprised if there were an Atari virus, for most of the reasons already mentioned here; additionally, I find that most of the programs I use on a regular basis don't like to work right if the program I ran before them has left anything in memory, therefore I have to turn the computer off and back on just to go from one program to another. I'd like to see a virus survive THAT! Besides, if nothing else, there just isn't a lot of memory available for a virus, even if one did get written! On the other hand, you could write a SIMPLE one that could be appended onto other, legitimate program files and go in and do nasty things... Would be hard for it to propagate, though, what with memory restrictions, constraints on system pointers, cycle-counting constraints on DLIs, VBIs, or any other attempted "behind-the-scenes" manipulations, the "noisy bus" I/O, and so on and so forth....

>I am getting desperate for the program that will allow me to copy any file from
>my disk drive to my tape drive. ...
> paul lozier

As far as I know there is no reason why you could not use the DOS
'copy file' command, and give C: as output file name. Alternatively,
a simple Basic program could also be used:

```
10 OPEN #1,4,0,"D:whatever"
20 OPEN #2,8,0,"C:"
30 TRAP 200
40 GET #1,X
50 PUT #2,X
60 GOTO 40
200 CLOSE #1
210 CLOSE #2
220 END
```

This would be a bit slower, but should work.

If you are talking about copying boot disks, as opposed to DOS files, things
get a whole lot more complicated, and you won't find a general purpose
program to do this job for you.

I have written a PD (simple minded, no macros, etc.) assembler for the 6502 that should not have any trouble running under SpartaDos (or 2.5, or ...). It has been distributed for several years by the DALACE club library and if anyone wants a copy I can post or mail it (the source is several files totaling about 300 sectors I think, the executable is about 25 sectors -- SD sectors that is). The syntax is mostly AMAC with a few extensions to handle code moved over from MAC65. Does anyone want to add macros or extend the object format to self-relocating code? Here's your chance!

1257. PD Runtime pack - Action!

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-26 03:40:53 UTC
From: curzon@kaoa01.dec.com
Message-ID: <8805260340.AA24374@decwrl.dec.com>
Source record: 116761

```
Here is Jeff Reister's PD Runtime package for the Action! 8 bit language.
To use it in the simplest form, simply add to the beginning of your Action!
program the line
INCLUDE "D:RUNTIME.ACT"
and compile as normal. If the compile is successful, the resulting file can be
run as a binary file (No Action! cartridge necessary).

Additional programs not included here because they are binaries:

RTSCAN.COM - run against your source file to produce a listing
showing which RUNTIME.ACT routines are actually required
by your program. Allows you to trim out unneeded
routines to save symbol table space, etc.
RTWRITE.COM - If you send the output from RTSCAN.COM to a disk file,
you can then run RTWRITE on that file -- it in turn
outputs the trimmed down version of RUNTIME.ACT for
you.

These should be available from any respectable Atari club library. Of
course, you don't need them for most programs, just include the full
RUNTIME.ACT and don't get fancy. The whole works is on the computer services
GEnie, Delphi, Compuserve.

1258. ACTION! Runtime Library Extractor

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-26 03:43:42 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8805260343.AA21785@mitre-bedford.ARPA>
Source record: 116762

As I have gotten several urgent requests for it, I am re-posting the ACTION! Runtime Library Extractor information that Paul van de Graaf posted some time ago.

The attached message is self-explanatory. If you own the ACTION! cartridge, the instructions Paul gives will enable you to extract a disk version of the runtime library contained therein. You will then be able to make standalone ACTION! programs that do not require the cartridge to be inserted when they are run. In my opinion, this is permissible under the doctrine of "fair use" copying for your own convenience. If you share copies of such programs with friends, you may be getting into a gray area, and if you SELL them, I would think you would be better off buying the rights to the official Runtime Library from OSS. In any case, these are just my own opinions, so make your own determination of legality before proceeding.

-John Sangster

Date: 22 Mar 86 05:14:10 GMT

Subject: At last! A free Action! Run-Time Library (LONG)

Copyright (c) 1986, Paul van de Graaf
Permission is granted for Usenet & Arpanet users to copy this article for their own use. It is NOT to be distributed beyond Usenet & Arpanet sites (or normal tributaries thereof); sold, or traded without permission from the author.

The reason for the above notice is that I am considering getting this article and programs published in either Analog or Antic. Consider this a Beta-Test of the article & programs. They will either be published in another form, or released into the public domain. I would especially like to keep them off of Compuserve et al., for the time being.

Here's the program you Action! programmers have all been waiting for!
A free Run-Time Library of sorts for the Action! language.

But first a few disclaimers:
1.) This run-time library requires at least 48K of memory. It will not run when cartridges are installed, as it uses memory from $A000 to $B5FF.

2.) The library has only been tested for version 3.6 of the Action! cartridge. To find out which version you have, check location $B000. It contains the version number in hex. If it's not $36, then the library might not work. I'd try it anyway, since it might work, or there probably is an easy patch. See the text below for more details.

3.) Since this library requires that you make a copy of part of the Action!
cartridge, there may be some issue of piracy. I consider this a legal
back-up copy of the cartridge as stated in the licensing agreement, but
OSS's attorneys might think otherwise. Proceed at your own risk!
I take no legal responsibility for your actions.

4.) Because the routines PrintF() and Error() have some bank-switching in them,
they do not work normally. PrintF() works fine, except when asked to
print CARDs in hex, it prints them in decimal. [ie. PrintF("%H",foo)]
FIXACT.ACT changes the PrintF routine to make it act this way, otherwise
it would lock up, since it tries to call bank-switched code. I personally
never cared for this routine anyway, because it always prints a leading "$",
and you can't get it to suppress leading zeros. I'm sure you could write a
better PrintF() yourself. The Error() routine works about the same as
before, but instead of returning to the monitor after an error, it returns
to DOS.

Introduction:

I wrote this library, because I can't understand why OSS decided not to include
a run-time library with the Action! system. The run-time library routines are
only about 2K of the cartridge. They could have easily made some facility to
link the routines into the code. Perhaps they were short on space in the
cartridge, or maybe this is some marketing ploy to sell run-time library disks.
I haven't seen or heard any details on the run-time library disk, other than
you can get one for $30.00. I'm sure their library is a much more elegant,
as I went the quick and dirty route. Instead of writing a full-blown linker
and relocator to link in the run-time library, I opted for a simpler approach.

How it works:

My home-brew run-time library consists of 4 programs:
RTL.ACT Sets up memory for the run-time library.
ACTION.COM A copy of part of the Action! cartridge saved to a binary file.
FIXACT.ACT Fixes the self-modifying and bank-switching code in ACTION.COM
CLEANUP.ACT Cleans up after the run-time library.

The library works like this: RTL.ACT is run first. It is a one-shot program
which makes your 48K or greater machine look like a 40K computer by closing
the editor, bumping down RAMTOP, and opening the editor again. It also sets
up the error handler, and opens the keyboard as channel 7. Channel 7 is opened
because the Action! cartridge keeps channel 7 open all the time, and some
programs take advantage of this channel. After RTL.ACT is run, ACTION.COM is
loaded, and the run-time library is in place. It's as if the cartridge is
inserted, except this cartridge can be written to and can't do bank-switching.
After ACTION.COM is loaded, a compiled Action! program can be run, and it will
call the library routines that were normally on the cartridge, but now have
been copied and loaded into RAM. After the compiled Action! program is run,
you have the option of running CLEANUP.ACT to reset the machine so it looks
like it has 48K of memory again.

There's just one problem, though. The Action! cartridge has some self-modifying
code in it that can alter the routines in the run-time library as it runs.

It works fine when it's in a ROM cartridge, but it gets messed up when in RAM. This code was put in to make life difficult for pirates who might be considering ripping-off the Action! cartridge. I took a disassembler to ACTION.COM and I'm fairly certain I've located all the self-modifying code. While disassembling I also located the bank-switching code mentioned above. FIXACT.ACT replaces the tainted code with NOPs, thereby de-fusing the logic bombs.

Contrary to what you might expect, you CAN write programs in Action! that will run without the run-time library. You can't call any library routines, do a multiply, divide, MOD, RSH, or LSH; use the trace or error facilities, or have a PROC/FUNC that has more than 3 bytes of parameters. These constraints make programming difficult, but not impossible. RTL.ACT is written in this manner. It uses CIO calls to do opens, closes and puts to IO channels, rather than calling the run-time library routines.

Dim the lights, it's time for the sermon:

I believe it's important to mention the distinction between what I'm doing here, and piracy. I am only making a backup of the cartridge, and this backup is taking the place of the cartridge when I want to run a program without the cartridge inserted. If the Action! system were better designed, I needn't bother with this. I don't think this constitutes piracy unless I give/sell a copy of the cartridge to somebody, or use it on a different computer. I only give the patches to fix code in the run-time library in FIXACT.COM-- NOT for the editor, monitor, or compiler sections of the cartridge. In fact after looking at most of the code in the Action! cartridge, I would guess any effort to pirate the cartridge, other than building a similar bank-switching arrangement, would greatly reduce the functionality of Action!. Besides-- you can get it for $29.00 at some mail-order shops. Despite their mistake with the run-time library for Action!, OSS is a quality software vendor, and they deserve our support.

Making the run-time library:

Step 1:
Go to DOS with the Action! cartridge installed.
Select the K command to write a binary file.
At the prompt: SAVE - GIVE FILE,START,END,(INIT,LOAD)
type: ACTION.COM,A000,B5FF

Step 2:
Compile RTL.ACT, and from the monitor type: W "RTL.COM"
Compile FIXACT.ACT, and from the monitor type: W "FIXACT.COM"
Compile CLEANUP.ACT, and from the monitor type: W "CLEANUP.COM"

Step 3:
Remove the Action! cartridge and re-boot the system.
(on the XL & XE be sure to press the Option key when booting)
Select the L command from the DOS menu to load a binary file.
At the prompt: LOAD FROM WHAT FILE? type: RTL.COM
The screen will clear, and you'll return to DOS.
DOS gets confused because the screen was cleared and the cursor was moved.

Press return, and DOS will redraw the menu and come back to its senses.
Select the L command again.
At the prompt: LOAD FROM WHAT FILE? type: ACTION.COM
After the file has loaded, select the L command again.
At the prompt: LOAD FROM WHAT FILE? type: FIXACT.COM
After the file loads and runs, select the K (binary save) command.
At the prompt: SAVE - GIVE FILE,START,END,(INIT,RUN)
type: ACTION.COM,A000,B5FF

Three ways to use the run-time library:

1.) Manually:

Boot DOS without any cartridges installed (press option while booting on an XL or XE). Load RTL.COM from DOS, then load ACTION.COM from DOS, and finally load the compiled Action! program you wish to run. This is rather tedious process, but it's ideal for quickly testing the run-time library.

2.) With an AUTORUN.SYS file:
Make a compound binary load file from DOS. Select the C command and
at the prompt: COPY--FROM,TO? type: ACTION.COM,RTL.COM/A
This will append ACTION.COM to the end of RTL.COM. When loaded with the L command, RTL.COM will now run the old RTL.COM program, and then load ACTION.COM. If you rename RTL.COM as AUTORUN.SYS, this process will automatically occur at boot time. After the boot, you can load compiled Action! files from DOS, and they should run properly. You probably would want to use this technique if you have a bunch of compiled Action! programs on the same disk.

3.) A fully linked file:
Take a file like the AUTORUN.SYS file above, and append your compiled Action! program to it. IE. choose the C command from DOS, and type "YOUR_PROGAM.COM, AUTORUN.SYS/A" at the prompt. If you want to have the run-time library clean up after itself when your program returns to DOS, you'll also want to append the CLEANUP.COM file too. IE. "C(opy) CLEANUP.COM,AUTORUN.SYS/A". You might want to change the name of the file to something other than AUTORUN.SYS, if you don't want it to run automatically at boot time. This technique has a disadvantage -- after all that appending, the load file gets quite large! I have tried to pare the size down a little by only saving part of the Action! cartridge. Still, the ACTION.COM file is much larger than the 2K of routines we need. The problem is that the run-time library is scattered throughout the address space of the cartridge, and it's too much trouble to save it in several fragmented files.

If it doesn't work:

tines by using the
monitor. ex. ? PrintF. A few routines can't be found this way. They are: the math routines: MULTIPLY, DIVIDE, MOD, LSH, RSH; a routine which saves parameters and checks for a break key abort when PROCs or FUNCs with more than 3 bytes of parameters are called, and a routine to print a PROC/FUNC name and its arguments when trace is set. The way I found the entry points

to these routines was to disassemble a compiled Action! programs which called these routines. Good Luck! Please send me mail if you find a patch to FIXACT.ACT which works for your version.

And now the programs:

After all this build-up, the programs are probably a let-down. They're quite straight-forward if you know the CIO routine. If you don't, you might want to get the technical notes from Atari (if they still sell them!). It probably will be easier to down-load them in one big file, and then hack it to pieces with the Action! editor.

I'd like to know if this library works with the other versions of the Action! cartridge. Send me mail if it works with your version.

Thanks,

I have been using Sparta DOS for a while, and twice I have seen a certain thing happen. It was fatal both times, and I never found out how it happened. I haven't been able to reproduce the error yet. This bug in Sparta DOS will rename many different files to the same name. I think it happened both times while using the ERASE command, so it couldn't have been a typo while renaming. What is even weirder is that both times the new filename was "SECTORS" or something like that. I KNOW for a fact that SECTORS was not a filename anywhere on the hard drive.

Now the first time it happened, it only goofed up selected files in a subdirectory (not all of them), but the second time it happened, it screwed up an entire partition on a hard drive. About 8 megs of files with the same name....

Has anyone had this problem? Does anyone know anything about it?

Subject: BBS Express Pro!

I work on a local bulliten board system up here, and we just went to Keith Ledbetter's BBS Express Pro!. My general observations are that it is really awesome, but since it didn't come with much MAC/65 support, I'm a little in the dark about adding modules to it. I do not know Action! and I don't care to learn, so while it isn't out of the question, I would rather use my "native tounge" to program in.

Does anyone out there have any good examples of MAC/65 source for use with Express Pro!? About all I have is a simple hi-lo number guessing game that I whipped up real quick. I know that Keith is planning on releasing some real MAC/65 support, but I am hoping that someone out there in net-land has something for me. Please share whatever you come with!

1261. Graphics Operating Environment

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-27 22:33:25 UTC
From: njd@ihlpm.ATT.COM
Message-ID: <1908@ihlpm.ATT.COM>
Source record: 116765

I saw a posting about this on Delphi this week, and thought that it may greatly interest the Atari 8-bit user community:

Merrill Ward and Associates, of Palm Springs CA says that they will introduce the "Graphic Operating Environment", a GEM-like program for the 8-bits at the June CES. It will be sold as a
supercartridge, and will work with a ST mouse, joystick, or just the keyboard. It will include "the operating system,"[?] a word processor, drawing program, printer drivers, an icon editor, and a number of fonts. Discussions are underway with Atari about bundling GOE with XE machines.

A demo version can be obtained on disk by sending $5.00 to:

Merrill Ward and Associates
255 North El Cielo Rd.
Suite 222
Palm Springs, CA 92262

If anyone out there is going to CES, please let the rest of us know if this thing is really shown, and how it looks.

Cross-posted to: comp.misc,comp.sys.atari.8bit,comp.sys.atari.st,comp.sys.amiga,misc.wanted

Please forgive the wide range and distribution; I'm running short on time and want to hit as many people as possible.

I've seen mention several times hither and yon, of "... the Consumer Electronics Show (CES) in Chicago this month (June)..." but no further data. Can someone please tell me WHEN and WHERE this thing is taking place? I've been wanting to get to one for years and this looks like my first decent "shot at it."

Any info on FUTURE CES's would also be appreciated.

Include any and all info on fees, ticketing (?), parking, qualification for attendance (can ANYBODY just walk in, or what?) etc. etc...

Thanks in advance. I don't read all the newsgroups this is posted to, so please E-mail instead of, or in addition to, posting a followup.

Good news for 8 bit computers users.

For the last two weeks Fredarated Electronics has been selling the
following:

1.) 800XL Computer
2.) XF551 Double Sided Double Density Disk Drive.
3.) XM301 300 baud Modem

All this for 199.00 plus a 50.00 gift cert.. So that means thar
you can get a new XF551 for less then 150.00.

A great deal!

Get one if there is a F.E. in your area.

1265. Intermittent Heat-Related System Failure

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-30 19:27:10 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <3204@bsu-cs.UUCP>
Source record: 116769

Greetings.

Regular readers of this group may recall my postings over the past several months, dealing with intermittent system problems which I attributed to my aging Percom AT-88 disk drive. Unfortunately, the problem has always been sporadic enough to elude simple cause-and-effect diagnosis, and the software which locks up has always been complex enough (AtariWriter, AtariWriter Plus, video games) that the problem "could be anything" in the system.

Last night, however, all of that changed. I've been working on a little graphics-demo program, in which the "main program" does the well-known "rainbow" effect with the "background" color, while a VBI routine "rotates" five players (yes, five) horizontally across the central portion of the screen. It's a short program, I understand it thoroughly, and it LOCKED UP on my computer three separate times when it absolutely should NOT have. (Code is below for those who want it.)

From this latest development, I've been able to deduce that yes, the problem IS heat-related. The first time this program locked up, the computer had been on most of the day, and a hot day at that. Thinking back, most of the other failures occurred when one or both of these factors was true. The clincher was when I let the program run all night. It ran fine for a half hour before I shut the monitor off at 2AM, then when I turned it back on at 10AM the background ripple was gone, the player graphics data was corrupted, and the program no longer responded to the "exit" command (START+SELECT+OPTION all pressed at the same time.) The "main program," in other words, had died. The VBI routine, however, was still running, rotating the players just as always. THAT seems as though it ought to be significant; can anyone be more specific?

On discovering this situation, I felt around the case (this is an 800, not an XL or XE) and found that the hottest place was in the right rear, where as I recall from years ago, the RF drive circuitry lies. (I'm using a monitor so the RF circuit is driving NOTHING; can that be enough of a problem to fry the rest of the machine?) The "personality board" and three RAM boards inside the main hatch (BACK of the cartridge slots) were warm to the near-touch, also.

There's a computer place north of here that for ten bucks will examine your computer and tell you what's wrong with it. I am thinking of taking this beast up there, but I sure don't want them to MISS anything. From what I've described, can anyone here suggest the most likely / common cause of this type of problem? I should point out that no one else I've known with an Atari (although most of them are XLs, not originals like mine) has any problem running the VERY SAME COPY of any of the programs that lock up on my machine.

Thanks in advance for anything anyone can say. The disk drive problem is one thing, but if my main box is fried that's another story entirely. SPARE

NO EXPENSE! etc.

Chris Chiesa
Ball State University
Muncie, IN

The following is the code for my short graphics-demo program. Put it on when you go to bed tonight, and see if it is still running properly when you get up tomorrow morning. If it IS, then I've got a problem. If it ISN'T then YOU'VE got the SAME problem.

1266. 2 questions

Newsgroup: comp.sys.atari.8bit
Date: 1988-05-31 00:38:20 UTC
From: wilmott@topaz.rutgers.edu
Message-ID: <May.30.20.38.18.1988.14439@topaz.rutgers.edu>
Source record: 116770

Greetings all. 2 quick questions:

1) I've heard rumours of a quirk with the new replacement drive for the good 'ole 1050 - namely that because of the fact that it is a double sided drive and because it makes use of the timing hole on the disk (which the 1050 doesn't), that disks which have been "notched" and flipped to use 2 of, can't be written to on the new drive. My question : If you insert one of these disks upside-down in the new drive, will the drive be able to READ it, or would you have to use a hole-punch on the jacket in the appropriate place to create a timing hole to make the drive happy (and make me unhappy! :-(

2) Has anybody heard any reports/rumours of when (if?) Datasoft thinks they'll be ready to release the next installment of Alternate Reality?

I would like to see this posted. It should probably be in this group.
If you don't post it, could you mail me a copy?

Yes, I'd be VERY interested in such a program. Don't know where you'd post it, although if you can look at a list of newsgroups (the file .newsrc in your main directory, usually) you can probably puzzle it out. I'd say it would depend somewhat on the nature and size of the posting: source vs. binary, and how long (a judgement call). Suggested search pattern:

Short sources: comp.sys.atari.8bit and comp.sys.ibm-pc (check this name)

Long sources: comp.sources.misc (check this name, there should be SOMETHING LIKE this available)

Binaries: your guess is as good as mine; depends a lot on how you plan to encode it for posting; if it's short, of course, see "short sources" above!

Hope this helps; I'd really like to see this program. If all else fails, e-mail me a copy at the address below, please.

OK, I think it's sorta short, and the alternatives may not get read by the
people who want it. (Donning my asbestoses in case someone strongly disagrees
with my size estimate!)

This is a "traditional" shar file with the MSDOS executable uuencoded on the
end.

This is a utility program that allows you to read, write and format diskettes
on an IBM PC or compatible in the MYDOS double density format for the Atari
8-bit computers. The utility does not support any of the 128-byte sector
formats, but the source is included (in case you come up with a way to add
such support). The program has been compiled with Microsoft C and MASM.

I hope you find it useful.

==========

```
#! /bin/sh
# This is a shell archive. Remove anything before this line, then unpack
# it by saving it into a file and typing "sh file". To overwrite existing
# files, type "sh file -c". You can also feed this as standard input via
# unshar, or by typing "sh READ.ME <<'END_OF_READ.ME'
```

```
XThe UTIL program is used to read and
Xwrite Atari double density diskettes
Xon an IBM-compatible computer. The
Xtwo source files for the utility are
XUTIL.C and ATARIO.ASM.
X
XEnter UTIL with no parameters and a
Xhelp message will be displayed. To
Xread, write or format a disk, enter
Xthe commands /R, /W or /I. The
Xcommand for displaying the directory
Xis /L. If the command line contains
Xa /B, the files will not be translat-
Xed to/from ATASCII (i.e., they are
Xbinary files). The command line for
Xall but the /W function will end with
Xa drive identifier (A:, B:, C: or D:)
X-- this is the ABSOLUTE drive number,
Xnot the one MSDOS uses. An external
X3.5" drive will usually be drive C:,
Xnot D: or E: or whatever DOS calls
Xit. Use the /L command until you are
Xsure you know which drive is which!
X
XTo write to the Atari diskette, the
Xdrive identifier is followed by a
Xlist of file names to be written to
Xthe Atari diskette.
X
X Good luck,
X Charles Marslett

1271. Atari Letter-quality Printer

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-03 18:22:29 UTC
From: lackey@Alliant.COM
Message-ID: <1907@alliant.Alliant.COM>
Source record: 116775

Well, I was walking through my local software shop last night, and, much to my amazement, I saw a few of the atari letter quality printers selling for $79.99!! Needless to say, it took me about 3 seconds to decide to buy one. (All I had was an even wimpier PCjr thermal printer I bought off the telephone auction on TV a few years ago for $30).

OK, it's a little slow. But it really works. On actual paper!

My question is, where do I find the replacement little ink things? I would like to collect up a supply, because stuff like that can start getting in short supply when things are past their prime :-).

-Stan

Hmm... this may be a good deal, but...

>My question is, where do I find the replacement little ink things? I would
>like to collect up a supply, because stuff like that can start getting
>in short supply when things are past their prime :-).

My question: did you buy the Atari 1027 Letter Quality Printer? If so,
this is a printer that Atari started making about 5 or more years ago
(before Tramiel bought the company) and no longer supports. (As far
as I know.) If it isn't the 1027 model, which model is it? I haven't
heard of any new Atari printers (aside from the XMM801/SMM801 dot matrix
printers and the in/famous Atari Laser Printer) since all the hype about
three years ago.

Good luck on finding supplies though; I think a couple of places that
might be able to help you out are B & C Computervisions in San Francisco
and a place called American TV (I think ... I don't have my Antic or
Analog magazines in front of me...) Both of these have advertised parts
and things for older Atari components, they should be able to help you
out.

Atari advertises in every issue of Atari Explorer. They currently list
ink rollers as "in stock".

FC100626 Ink Rollers $ 3.95
5 Ink rollers for $ 10.00

California residents add 7% sales tax.
S & H - under $50.00, add $ 3.50
over $50.00, add $ 5.00
over $100.00, add $ 7.00
outside USA add $10.00

Order from Atari ST, Dept. M9
P. O. Box 61657
Sunnyvale, Ca. 94088

1276. Cartridge Update - Centipede, Battlezone

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-06 00:21:14 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <3215@bsu-cs.UUCP>
Source record: 116780

In a recent series of articles here, I discussed my explorations of Atari's CENTIPEDE game cartridge, vis-a-vis making a disk-based copy for self-educational purposes. At that time, I had been able to copy the 8K of data from cartridge ROM to disk, load the same data back into RAM at the original addresses, and get a "partial" execution of the "intro" portion of the program. Attempts to continue on into the "game" portion of the program resulted in system freeze-up.

I asked for suggestions as to why this might be happening, i.e. what techniques Atari might have used to discourage RAM execution while allowing ROM execution. Thanks to all who responded, especially Hans Breitenlohner (hans@umd5.umd.edu), Ray Wilmott (wilmott@topaz.rutgers.edu), and Andy A. Lee (alif+@andrew.cmu.edu). After printing, saving, and absorbing (!) your comments, I'm pleased to announce that I was finally SUCCESSFUL in getting that disk version running.

In the interest of helping others as I have been helped, here then is a brief summary of what I found in CENTIPEDE. Following THAT, I will also comment on the results of similar investigations into the new BATTLEZONE cartridge.

CENTIPEDE:

Centipede turns out to be an 8K cartridge, performs NO esoteric bank-switching or relocating, etc. Execution occurs within the standard left-cartridge (400/800; the ONLY cartridge, XL/XE series) address range of $A000 - $BFFF. One of the first things the program does is to establish its own Vertical Blank Interrupt service routines, which appear to be concerned in part with shadowing console key readings ($D01F-- CONSOL) into RAM. This incidentally locks OUT such standard functions as keyboard-reading and the like, making single-step debugging more or less impossible (analysis proceeded by looking at static disassembly output).

Protection is implemented at two separate points in the code. The first comes at address $A087, where LSRs are performed on data within the cartridge space itself. The address being LSR'd turns out to be the entry point for the main game-playing routine; if the program is executing from an inserted cartridge, the LSRs have no effect on the data/code being LSR'd -- but if it's executing from a RAM copy, this effectively "trashes" the code at that address. The second line of defense (so to speak) appears around $A151, where once again an LSR is performed on cartridge-space memory. This time, the data BEFORE the LSR is compared with that AFTER the LSR, determining quite neatly whether the environment is RAM or ROM; if ROM, a JSR is performed to what seems to be the main game routine; if RAM, a JMP is performed to the SAME address. The JMP, of course, fails to stack a return address, and when execution hits an RTS, there's noplace to return to -- I imagine execution ATTEMPTS to continue with

whatever follows the "jump to loaded application" portion of the operating system!

BATTLEZONE:

After the success with Centipede, a friend and I decided to take a look at the new BATTLEZONE cartridge. First off, for those who've been wondering, I can personally guarantee that it DOES run on BOTH the 800XL and the original 800 -- no matter what the sellers of the XEGS may tell you! This in itself is significant, for reasons I'll get to momentarily.

Battlezone banks into memory looking like a 16K cartridge: addresses $8000 through $BFFF decode into cartridge ROM. Execution begins at $B000, and IMMEDIATELY things get complicated.

Hans Breitenlohner explained to me a little about the role of location $D500 in implementing more-than-16K cartridges; basically, what seems to happen is that storing a value into $D500 affects what appears at addresses $8000-$9FFF (the RIGHT cartridge space, 400/800). Specifically, it acts like a "bank select" register. Storing $00 at $D500 results in ONE set of data in $8000-$9FFF; storing $01 at $D500 results in a totally separate set of data at those addresses. (Note: I am ASSUMING, at present, that $D500 controls the whole ball o' wax, toggling 8K blocks in and out all at once. Hans, you mentioned that addresses $D500-$D5FF are actually involved in this - that would imply that the banking segment size was much SMALLER; can you confirm or refute? Anyone else?) Initialization of BATTLEZONE consists of storing #$00 at $D500, copying 8K of data from the bank at $8000-9FFF, to RAM at $4000-$5FFF, then storing #$01 at $D500 and copying a second 8K to $6000-$7FFF, then storing #$02 at $D500 and performing a JMP $4000 . Whew. That cartridge copies 16K of itself into RAM, and sets up a THIRD 8K for access in ROM, JUST in the INITIALIZATION routine! Skimming the code, I find that $D500 is manipulated "on the fly" during execution of the program, banking in I know not how many more 8K chunks at various times.

The thing that I find interesting about this, is that it works just as well on my original-series 800, as on my friend's 800XL. This makes the $D500 bank-switching scheme something of an "undocumented" feature all the way from the beginning of Atari computers! MAPPING THE ATARI says absolutely NOTHING about location $D500 (in fact, nothing about any address between $D40F and $D800) in the "main body," nor in Appendix 11 ("Addenda and Errata to the First Edition"), of the "Revised Edition." The only mention of this little marvel is made in Appendix 12, which states, in part, that it is "... unused in both XL and 400/800 models"! The implication, which I think I've just disproved, is that didn't even EXIST until the XE series! And there's NO hint of the bank-switching capability.

(Oddly enough, I had a hint of this while trying to track down the intermittent heat failure about which I posted last week -- I noticed in the schematic for the 800 "personality board," that a "$D5xx" line comes out of the address multiplexer chip. Sounds like that might have something to do with all this, eh? There was ALSO a "D6xx" line! What might THAT one do? Any

takers??)

Hope this is of interest to someone; note that my investigations are for the purpose only of understanding my machine, and educating myself and friends in that direction.

Chris Chiesa
graduate of Ball State University, Muncie, IN

the effect of
this is a "delayed effect" defense, since everything goes as intended until the CPU hits an RTS instruction: if the JSR was performed, control returns to the instruction following the JSR, and Centipede proceeds unhindered. If the JMP was pwe

space, using RAM of course fo

1277. Summer C.E.S. Highlights

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-06 05:01:17 UTC
From: rich@jolnet.UUCP
Message-ID: <592@jolnet.UUCP>
Source record: 116781
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

Greetings from Chicago!

I really hate to do this to you all but here are the cold hard
facts.

1) This year the CES was geared strictly for games. (:<)

2) There were no new software packages displayed for the ST line.

3) As of Sunday, the second day of the show, the attendance was about half
of what it had been in years past. (The show is a loser)

Now for some interesting tidbits......

The UN*X box will not be introduced until next year. The marketing
strategy goes something like this:
"If we introduce the Unix box now we will probably not sell another MEGA
and we have lots of those around."

The PC has to go through a redesign. It seems that with all of the
functions that were put on the mother board, the assembly plant could not get
the insertion machines to work on the densely populated boards.

There is a new development package for the 2600 and 7800 machines.
It consists of an assembler and rom emulator. The system utilizes an ST.

Other than that there is not really anything else new. I will be able
to tell more after the annual CLAUG/Atari roast dinner.

later,

Rich Andrews

1278. Do you like smooth scrolling?

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-06 05:12:59 UTC
From: charles@c3engr.UUCP
Message-ID: <2853@c3engr.UUCP>
Source record: 116782

I have taken the VT52 emulator written in Action! and posted here a year or so ago and modified it as follows:

1) Added XON/XOFF flow control due to overruns at 1200 bps.

2) Modified the display code to use the display list to scroll the screen and insert/delete lines for much greater speed (and making 1) above unneeded...).

3) Changed the emulation to Televideo 925 for some obscure reason that escapes me at the moment.

I intend to post the finished product in the not-too-distant future, but I was contemplating adding one more feature: smooth scrolling. Those four-pixel-wide characters are hard to read with jump scrolling, but since some folks may not like it, I thought I'd ask whether the folks out there looking for an 80-column emulator would want it to have this feature or not.

Please E-mail your responses and I'll summarize. Thanks.

>telephone?

Only if the modem specifically wants it that way. Usually modems (like the Atari 1030, XM301 and SX212 and nearly all Hayes-compatible modems) want a line-in from the modular plug (RJ-11) that you are familiar with from home, perhaps. Dire circumstances may await your modem if it wants a line-in. Some older modems worked via the handset cord (in a way similar to the old acoustic couplers) but most simply want the line-in.

>I'm asking this because the modular phone in my new dorm room is
>hard-wired into the wall. Arrrghhhh. (No, I can't ask them to re-wire it.

True, but you can go ahead and wire in a modular plug anyway--if you are willing to accept the consequences of the dorm staff finding out and/or the telco. Actually, depending upon what phone you have, you can install/deinstall your contraband modular plug without them knowing about it!

If you are interested further, drop me a line describing the phone you have and the particular installation of the phone.

>Everybody does it anyhow, at least in the dorms with jacks instead
>of hardwired phones. Arrrghhhh, again!)

I did, but then OSU installed phones with extra modular jacks :-)

DISCLAIMER: My views represent me and not those of OSU, the OSU Residence and Dining Halls nor the OSU College of Business; nor the views of any of the Communist governments of the Warsaw Pact. (Which are similar to all the above.)

|>A while ago someone mentioned that there were some serious bugs in the
|>Atari Macro Assembler. Since I've just started using it, what are these bugs?

Ugh...it has been so long ago that I don't remember them all!! I'll try to recap what I can:

1. AMAC does NOT work under SpartaDOS. They do something tricky with the I/O that most programs don't do.

2. I've seen symbols get "lost" somewhere when you write large programs. By lost I mean they get undefined, etc. Sorry, I can't elaborate further, but I do know I spent many hours pulling my hair out on this one.

3. (not a bug) Larger programs get tedious in the edit..assemble.. run..boot.. cycle. You need to load a separate editor, and AMAC itself isn't small.

Unfortunately, these are the major points I can remember. I started using MAC-65 and found it was MUCH easier to use than AMAC. There are a couple of things missing in MAC-65, but assembly time is reduced TREMENDOUSLY using MAC-65, it works under SpartaDOS, it has a built-in editor -- all in all I found using MAC-65 a pleasure. I recommend it over AMAC if at all possible.

Atari advertises in every issue of Atari Explorer. They currently list
ink rollers as "in stock".

FC100626 Ink Rollers $ 3.95
5 Ink rollers for $ 10.00

California residents add 7% sales tax.
S & H - under $50.00, add $ 3.50
over $50.00, add $ 5.00
over $100.00, add $ 7.00
outside USA add $10.00
```

Subject: Do you like smooth scrolling?
Message-Id: <2853@c3engr.UUCP>
Sender: info-atari8-request@score.stanford.edu
To: info-atari8@score.stanford.edu

I have taken the VT52 emulator written in Action! and posted here a year or so
ago and modified it as follows:

1) Added XON/XOFF flow control due to overruns at 1200 bps.

2) Modified the display code to use the display list to scroll the screen and
insert/delete lines for much greater speed (and making 1) above unneeded...).

3) Changed the emulation to Televideo 925 for some obscure reason that escapes
me at the moment.

I intend to post the finished product in the not-too-distant future, but I was
contemplating adding one more feature: smooth scrolling. Those four-pixel-
wide characters are hard to read with jump scrolling, but since some folks may
not like it, I thought I'd ask whether the folks out there looking for an 80-
column emulator would want it to have this feature or not.

Please E-mail your responses and I'll summarize. Thanks.

I have seen at least two ways to handle this problem. If you have a standard round mouthpiece (removable) on the phone, you can get a device that replaces the mouthpiece and has a modular phone jack built-in.

The other way is a device that Radio Shack sells that slips over the earpiece and the mouthpiece and basically converts your direct connect modem into an acoustical modem. It costs $49.95 according to the 1988 catalog.

> Is plugging the modem into the handset cord safe?

I don't believe that it will work.

>
Not true. I talked to several third party software suppliers and looked at what they had new for the ST. There is plenty new, both entertainment and productive software. Atari chose not to display the ST to any extent, probably because they are emphasizing the ST at COMDEX now. I was disappointed that there was no display of software or hardware for the 8bit computer line, though. No really good reason was given either. A lame excuse, such as "we tend to alternate, one year emphiasing computers and next year the game sytems". This isn't true, because I have been at the CES for the last several years and the computers have always been a part of the show.

> 3) As of Sunday, the second day of the show, the attendance was about half
> of what it had been in years past. (The show is a loser)
>
Maybe, but Saturday was pretty crowded and Monday was also plenty busy for a Monday at the CES. I do think that more of exhibiters are choosing other shows to highlight their wares. The movie software companies had a very small showing except for the "blue" movies. They are using a Video show as their vehicle of choice.

> Other than that there is not really anything else new. I will be able
> to tell more after the annual CLAUG/Atari roast dinner.

1290. OMNIVIEW vs. eyes

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-09 22:40:16 UTC
From: njd@ihlpm.ATT.COM
Message-ID: <1929@ihlpm.ATT.COM>
Source record: 116794

I have a few of questions to ask of anyone out there who uses OMNIVIEW:

1) Does OMNIVIEW's 80-column display cause you significant (to you) eyestrain?
(In my case, it usually does not.)

2) If the answer to (1) is "Yes," has it been enough to stop you from using
OMNIVIEW?

3) If you have seen the XEP-80's display, is it a lot better, or only
marginally better?

4) Do you plan to switch to using an XEP-80 someday?

I am asking these questions because I got into a discussion with Matt Ratcliff
on DELPHI about OMNIVIEW and the XEP-80, and I wanted to know how you all
feel about it.

To: info-atari8@score.STANFORD.EDU
X-Vms-To: IN%"atari"

1) Does anyone know where the bytes that contain the maximum and minumum
ATASCII values for filenames are in DOS 2.5? I found the DOS 2.0S locations
in "Mapping The Atari", but they apparently aren't the same in DOS 2.5.
(If anyone should want the DOS 2.0S locations, or the location of the
wildcard character, for any reason, just let me know.)
2) To go along with my planned lower-case copy of DOS, I'm hoping to convert
Atari BASIC to lowercase. I know where all the token tables are, but
I need to know how to make a file that will load and run properly. The
main thing I need to know is how to make the system think that there
is a cartridge installed and not overwrite my RAM copy of BASIC. Is this
```

possible?
3) A bit of weird trivia: I've been told that it is possible to load DUP.SYS
into AtariWriter and change the menu to anything you want. AtariWriter
will allegedly not destroy the non-ASCII characters in the remainder
of the file.

>... serious bugs in the Atari Macro Assembler ...

I have used it quite a bit. I have been a macro hacker since PDP-11's, and when I found the assembler cheap, I thought I'd died and gone to heaven.

Anyway, I have found two bugs.

1. There is something wrong with page control. I have not been able to find a fix. On my printer anyway, it makes pages too big - larger than a standard sheet. As I say, this may be an artifact of my printer (the little thermal printer over-produced for the PCjr.)

2. There were cases where it would not accept a macro name that followed a label - it would try to match it to a 6502 mneumonic. Putting a colon after each label made this one go away.

The only other "bug" that annoys me is that it doesn't run under SpartaDOS. I suspect that this is due to INCLUDE's - my guess is that the assembler does something funny to allow it to have MANY files open, so that INCLUDE's can be many levels deep. I suppose this can be tested by assembling a source that has no INCLUDE's, and seeing if it works. This is no good for me as a fix, because I have standard macro- and system definition- files, and also my editor can only handle text files that are under 16K in size.

If&when Atari comes out with an OS that supports the XF551, I shouldn't need SpartaDOS anymore and this problem will fix itself.

Speaking about dying and going to heaven... has anyone tried the new cartridge-
based SpartaDOS? I understand it is huge, and turns itself on and off to
give the user more RAM, while providing much more functionality. What's the
deal?

I have been interested in SpartaDOS X for a long time. I called both the
ICD order line and their BBS yesterday. The X cart. is NOT released yet, but
is expected at any time. One point to note for those who read the SpartaDOS
technical specs: the X will no longer use the vectors under the OS. I heard
mention that there would be a translator for those programs that need them.
This will probably make it compatable with Turbo Basic XL and other programs
that use the OS RAM space.
As far as the bank selecting in the cart., it must be pretty complex to
handle banking 64k ROM as well as switching in the piggybacked cart.
I will probably pick up the X as soon as it is completed. Unfortunately,
by that time, my account here will expire. I should be back in the fall to
report on the plusses and minusses (sp?) of this new product.

I think you mean DOS, not OS. Atari is supposed to be about ready to release
ADOS. Recent buyers of the XF551 are still getting Atari DOS 2.5 though.

The Beta versions of SpartaDOS-X cartridges are just now going out according
to ICD. If all goes well, they should be available in 2 to 3 months. I have
a one page sheet that ICD posted to their BBS and I have included it below.
It doesn't say anything about turning inself on and off.

==========

SpartaDOS X

Just what your 8-bit has been waiting for...a cartridge based DOS which
increases the power of your computer and includes an abundance of features
such as automatic Ultra Speed I/O with the Indus GT, US Doubler, and High Speed
on the new Atari XF551. SpartaDOS X is a fantastic new version of its disk
based cousin.

Even though SpartaDOS X is a 64K cartridge, it requires no memory from your
computer. You may piggyback another cartridge on top of the SpartaDOS X
cartridge and operate just as if you had booted from disk -- except much, much
faster. Here are just a few of the advanced features found in this cartridge
based DOS.

High Speed drive access with US Doubler, Atari XF551, and Indus GT
drives.
New improved menu program. Shows entire directory tree and performs
multi-file operations.
Supports up to 1 meg of internal memory as a RAMDISK.
The Lowest MEMLO of any DOS!
Powerful file loader supports relocatable files and symbol linking.
All new command processor includes parameter passing on batch files,

user definable prompt, and search file paths.
Commands now allow MS-DOS syntax!
The most commonly used commands are built right into the cartridge!
Atari 800 support with Axlon compatible upgrades.
Built in, all new formatter pops in with an XIO#254.

SpartaDOS X runs on an 800XL, 1200XL, 600XL (with expanded memory), 65XE, 130XE
800XE, the XE Game System, the old 800 with Axlon compatible RAM upgrade.

NOTE: SpartaDOS X will become available in June 1988. ($79.95 MSRP)

[not true, more like September 1988 - kk]

1294. ACTION PD RUNTIME

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-10 13:43:56 UTC
From: curzon@kaoa01.dec.com
Message-ID: <8806101343.AA23500@decwrl.dec.com>
Source record: 116798

Sorry if you saw this before... seems it didn't make it some places.

There are 2 runtime packages (at least) for Action! The one that
was sold by OSS (and now presumably by ICD Inc) is the original by Clint
Parker. It is not PD. The other one I did a quick review of last year:

The other (PD) package is by Jeff Reister (sp?) of Mount Vernon,
Washington. It includes an adaptation of the ST Reversi game published
by Analog, and a font editor, along with their source codes, and the
assembler sources for the runtime package code.

The actual runtime package is contained in one relatively short file
(RUNTIME.ACT). It seems to be quite a bit more compact than the OSS
runtime package. There is also a program RTSCAN.COM (with sources) that
scans 1 or more source code files, and compiles a list of each of the
RUNTIME symbols that will be required. The list can be output to any
device. It lists symbols in the same order as they appear in the
RUNTIME.ACT file, and the number of calls made to each. Then it is
simple to load a copy of RUNTIME.ACT into the editor, and kill all the
unused routines/variables.

Another author (name escapes me) wrote a program call RTWRITE,
that will take the output from RTSCAN (disk file) and write out the
minimum runtime package for you.

In all, this package makes less demand on your symbol table capacity
than the OSS package (fewer symbols). And, RTSCAN/RTWRITE makes it easy
to include only the direct and indirect routines needed, to make your
runable binary file as small as possible, and minimize symbol table
demands.

If you encounter symbol table capacity problems anyway in compiling
a very large program, this package does not include a routine to
increase symbol table space (like BIGST.ACT distributed with the OSS
package), nor does it have documentation on exactly what system
variables need to be changed.

However, BIGST.ACT was released to the world by Clint Parker's BBS,
as copyright but to be freely distributed, so that could be used in
conjunction with this PD runtime package.

The package comes with a notice that although this runtime package
is PD, Action! programs can still not be sold for profit unless cleared
with OSS Inc. [PROBABLY ICD INC - NOW]

It is a very fine package, and a definite improvement over the OSS
package in ease of use-- no bugs found yet.

```
[I have since used the PD runtime package on a couple of small
programs-- it works great...]

1295. DUP.SYS and Atariwriter

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-10 17:53:00 UTC
From: PHR140@URIMVS.BITNET
Message-ID: <8806102101.AA28977@ucbvax.Berkeley.EDU>
Source record: 116799

You can load the DUP.SYS file into Atariwriter and change the menu, I have done that before. The only thing that you have to make sure of is that you don't delete or add even one single byte, or the system will crash!! This is harder than it sounds, because of the word wrapping.. Actually, it is easier to make these changes with a disk editor because you don't have to worry about the word wrap.

1296. Re: modem connections

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-10 23:24:03 UTC
From: neil@atari.UUCP
Message-ID: <1072@atari.UUCP>
Source record: 116800

In article <8806062023.AA09302@ucbvax.Berkeley.EDU>, SHAFFERJ@BKNLVMS.BITNET ("Jim Shaffer, Jr.") writes:
> Does anyone have a non-permanently-damaging way of connecting a modem to
> a telephone that's hardwired to the telephone line?
> The telephone is modular; there's just no jack.
> Is plugging the modem into the handset cord safe?

The easiest way is to purchase a cable with a modular plug on one end and half-moon shaped connectors on the other.

Open up the phone housing by loosening the screws, then loosen the screws for the red and green wires. Attach the red and green wires on your cable, and screw the case back together. You'll end up with a wire coming out of some part of the case, which you plug into the modem.

Usually red goes to red and green to green, but sometimes you need to swap them.

This is what I do when I'm on the road in a non-modular hotel room.

1297. 800xl's....anyone?

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-10 23:32:08 UTC
From: wilmott@topaz.rutgers.edu
Message-ID: <Jun.10.19.32.04.1988.12464@topaz.rutgers.edu>
Source record: 116801

A recent message in this newsgroupd which stated that Federated
was selling XF551 & 800XL's as a package for $200 (or whatever)
prompts this question: Does anybody know of any mail order places
(since there are no Federated's here on the east coast) which still
have a few 800xl's left in their warehouses? I assumed they were
all gone long ago, but if Federated is selling them yet, I guess
there still may be some out there somewhere. I love my 4? year old
800xl, and would like to get hold of a "backup" (in case mine dies,
....or maybe to run a BBS?....) if at all possible.

-Ray

Atari advertises in every issue of Atari Explorer. They currently list
ink rollers as "in stock".

FC100626 Ink Rollers $ 3.95
5 Ink rollers for $ 10.00

California residents add 7% sales tax.
S & H - under $50.00, add $ 3.50
over $50.00, add $ 5.00
over $100.00, add $ 7.00
outside USA add $10.00
```

Order from Atari ST, Dept. M9
P. O. Box 61657

I have seen at least two ways to handle this problem. If you have a standard
round mouthpiece (removable) on the phone, you can get a device that replaces
the mouthpiece and has a modular phone jack built-in.
```

The other way is a device that Radio Shack sells that slips over the earpiece and the mouthpiece and basically converts your direct connect modem into an acoustical modem. It costs $49.95 according to the 1988 catalog.

> Is plugging the modem into the handset cord safe?

I don't believe that it will work.

Subject: OMNIVIEW vs. eyes
To: info-atari8@score.stanford.edu

I have a few of questions to ask of anyone out there who uses OMNIVIEW:

1) Does OMNIVIEW's 80-column display cause you significant (to you) eyestrain? (In my case, it usually does not.)

2) If the answer to (1) is "Yes," has it been enough to stop you from using OMNIVIEW?

3) If you have seen the XEP-80's display, is it a lot better, or only marginally better?

4) Do you plan to switch to using an XEP-80 someday?

I am asking these questions because I got into a discussion with Matt Ratcliff on DELPHI about OMNIVIEW and the XEP-80, and I wanted to know how you all feel about it.

|>A while ago someone mentioned that there were some serious bugs in the
|>Atari Macro Assembler. Since I've just started using it, what are these bugs?

Ugh...it has been so long ago that I don't remember them all!! I'll try to recap what I can:

1. AMAC does NOT work under SpartaDOS. They do something tricky with the I/O that most programs don't do.

2. I've seen symbols get "lost" somewhere when you write large programs. By lost I mean they get undefined, etc. Sorry, I can't elaborate further, but I do know I spent many hours pulling my hair out on this one.

3. (not a bug) Larger programs get tedious in the edit..assemble.. run..boot.. cycle. You need to load a separate editor, and AMAC itself isn't small.

Unfortunately, these are the major points I can remember. I started using MAC-65 and found it was MUCH easier to use than AMAC. There are a couple of things missing in MAC-65, but assembly time is reduced TREMENDOUSLY using MAC-65, it works under SpartaDOS, it has a built-in editor -- all in all I found using MAC-65 a pleasure. I recommend it over AMAC if at all possible.

Subject: DUP.SYS and Atariwriter

You can load the DUP.SYS file into Atariwriter and change the menu, I have done that before. The only thing that you have to make sure of is that you don't delete or add even one single byte, or the system will crash!! This is harder than it sounds, because of the word wrapping.. Actually, it is easier to make these changes with a disk editor because you don't have to worry about the word wrap.

> Is plugging the modem into the handset cord safe?

The easiest way is to purchase a cable with a modular plug on one end and half-moon shaped connectors on the other.

Open up the phone housing by loosening the screws, then loosen the screws for the red and green wires. Attach the red and green wires on your cable, and screw the case back together. You'll end up with a wire coming out of some part of the case, which you plug into the modem.

Usually red goes to red and green to green, but sometimes you need to swap them.

This is what I do when I'm on the road in a non-modular hotel room.

Since I know some of you guys at Atari read this newsgroup, I just wanted to voice a request of mine to Atari Inc. : please market the light gun for us 8-bit computer owners. I'd love to be able to play the new software available for the XEGS (I've heard Crossbow is coming?...), but since I already own 2 8-bit computers, I'm certainly not about to buy another console just to get the light gun! Come On Atari and market the light gun seperately for people like me!

-Ray

I was told by someone from Atari at their booth at CES that the light gun was already shipping and available in limited quanities. You might want to check with whomever you usually get hardware from. In the meantime, below is a list of available (or soon to be) cartridges for the XE Game System. These are all being released by Atari, even though several were originally by some other company. The only third party cartridge software that I hear rumors of is 'California Games' from Epyx, but it wasn't announced at CES, so it isn't on my list. If you see any obvious errors, please let me know. All the information came from Atari press releases and literature I picked up.

1306. OMNICOM use

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-20 17:04:55 UTC
From: abrams@community-chest.mitre.ORG
Message-ID: <8806201704.AA20010@chance.mitre.org>
Source record: 116710

I use OMNICOM with a B/W 11 inch TV. I previously used VT10SQ.
I have tried several TVs around the house and do find differences. I
settled on one which has contrast, focus, and brightness on the front.
I find that I have to adjust these controls as well as the tuning when
switching programs. My daughter uses Atariwriter, I use XLEnt First
Word. All three programs require adjustment for best viewing.

I have no trouble with eyestrain using OMNICOM. It's a little harder
to read than the Amdek monitor I have in the office, but not enough me
make me consider upgrading from my Atari 400!

From: ajb@cornea.mitre.ORG
Message-ID: <8806211251.AA18976@retina>
Source record: 116712

Since it appears that Neil Harris is still listening to our discussions,
I will repost the question that as yet remains officially
unanswered. Neil, if you're out there, how about an answer !!!

What all of us out here with older machines (e.g. 800) want to know is:
Which machines will successfully run the new xe-game cartridges.
For instance can I run ball-blazer on my 800 ?
Can I run it on my 600 with only 16k ram ?

From: rich@jolnet.UUCP
Message-ID: <611@jolnet.UUCP>
Source record: 116713

I actually have 2 1450XL systems for sale......

The first is a 1450XLD complete for sale. It includes the twin
disk drives, case, power supply, and is in perfect condition.

The second is a 1450XL and is less case, power supply, and disk
drives.

Both units have the on-board 300 baud modem and speech synthesizer.
Both units work fine.

I am asking $300.00 OBO for the 1450XL and $1000.00 OBO for the 1450XLD.

Rich Andrews
...killer!jolnet!rich

> What all of us out here with older machines (e.g. 800) want to know is:
> Which machines will successfully run the new xe-game cartridges.
> For instance can I run ball-blazer on my 800 ?
Yes.

Here is our current list of which XE supercarts will or will not work on an old 800.

WILL work on 800	Will NOT work
BATTLEZONE	LODE RUNNER
STAR RAIDERS II	FLIGHT SIMULATOR II
BUG HUNT	MIDNIGHT MAGIC
BLUE MAX	FOOD FIGHT
ARCHON	HARDBALL
BARNYARD BLASTER	FIGHT NIGHT
RESCUE ON FRACTALUS	ONE-ON-ONE
BALLBLAZER	
NECROMANCER	
DESERT FALCON	

> Can I run it on my 600 with only 16k ram ?
No. The goal is to provide the best games possible, for the widest range of machines practical. The large numbers of XL/XE machines out there mean they are the best targets for game development, with 800 support a worthwhile goal if it does not unduly compromise the game.

Jim Tittsler, Systems Engineer, Atari Corp. {portal, ames}!atari!jwt

What!!?? You mean these legendary machines actually existed??!! I remember way back about 5-6 years ago when these were nothing more than rumors coming from Atari. I didn't know they actually produced any. Or was the date on top of Rich's message "April 1" :-)

P.S. This is my first ever posting (I've been trying for a long while. Hope it makes it this time)

> Which machines will successfully run the new xe-game cartridges.
> For instance can I run ball-blazer on my 800 ?
> Can I run it on my 600 with only 16k ram ?

I tried to reply by mail but got bounced by the friendly daemon. Here goes:

I am not online here very often. Many other things going on, and the
engineering group seems to be offering good support here these days.

Carts that are 800-compatible are Battlezone, Star Raiders II, Bug Hunt,
Blue Max, Archon.

Ones that will NOT work are Lode Runner, Flight Simulator II, and Midnight
Magic.

The above information covers the first release of carts only. I will see if
we can get you an update on more recent releases.

Also, we list the system requirements on the cart's box. If it lists the
800, it is compatible. If the 800 is NOT listed, it is NOT compatible.

1315. RGB <--> Atari SETCOLOR conversion?

Newsgroup: comp.sys.atari.8bit
Date: 1988-06-28 23:50:43 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <3357@bsu-cs.UUCP>
Source record: 116719

Lately I've gotten interested in the "GIF" file format for "universally standardized" graphics (picture) files, and am considering writing a GIF viewer for the Atari 8-bit computers.

However, part of the information in a GIF file is a "color pallette" describing each of the colors to be used, in percentages of Red, Green, and Blue. The GIF standard states that, in the event that the precise RGB colors designated in the file can't be specified on the display hardware, a "predefined" palette should be used, coming "as close as possible" to the RGB spec.

Does anyone have information regarding the equivalence of Atari's "color 0 through 15, luminance 0 through 15" to percentage-mixtures of pure red, green, and blue? Failing that, can anyone suggest a workable way of determining same?

Thanks in advance,

Chris Chiesa

Will the supercarts work on a 1200xl? I would especially like
to know about the games that were written by Accolade. A while ago
I had baught one of their games at toys-r-us, and it wouldn't run.
The screen would go black, and the two leds (L1 and L2) would blink
alternately. Luckily, this happened before they changed their policy
on software returns.. I got my money back, and the woman at the desk
said "I guess it didn't like your computer." Interesting comment, I
thought....
I can't remember the name of the game off hand, but it was a flight
simulator which simulated bombing missions (I forget from what war).
Once these games are put into supercart. format, will they run on the
1200xl, or will they still be incompatable?

yes there were a few of the 1450 systems made. They had to exist so that pictures for advertising could be made.

Engineering also had to have some made so that developers sould start writing applications for the voice syth. One developer that actually had one was Dave Small (at least i think it was dave).

Likewise! I've been into stereo all my life, have done stereo in various forms
on computers (including a "cross-eye"-viewable stereo drawing program right h>
here on my good ol' Atari), and would *LOVE!* to have a pair of those "glasses"
to mess with!

Count me another vote in favor of marketing 'em separately!

Can you advise if the files are compatible with ARC for the ST and IBM
using CRUNCH? I was able to look at the ARC file which was supplied.
Was this file CRUNCHED with the AlfCrunch? If so MANY thanks. One other
question. Are sources available? I am working on a GIF viewer. and the GIF
pics are LZ compressed. IF they are maybe I will have a go at making a GIF
viewer. If anyone else has worked out a Viewer for GIF, or would like the
Documentation explaining the format of GIF, please advise. Thanks.

A friend of my just bought a left over 1200xl and we too were concerned if it would work with the new supercarts....Wel we tried a few games and sure enough it worked like a charm. The only supercart we tried was Blue Max and it worked fine. The rest of the games we tried were the standard carts like Pacman etc. Hope this eases some of your concerns.

BTW anyone out there in NET LAND know if Commnet Systems the maker of Forem are still in existance?? I'm trying to purchase a version of Forem to run on the 8 bit but can't obtain a copy anywhere. I've been looking for messages on the net by Matthew Singer the author of Forem but have not seen any message from him either. Any help on this would be greatly appreciated.

Matt Hetman

1323. Re: Daisy-Dot II and 24-pin printers..

Newsgroup: comp.sys.atari.8bit

Source record: 116727

Speaking of Daisy-Dot II, does anyone know if there is a version for 24-pin printers? I saw enough using 9-pin emulation on my 24-pin Fujitsu printer to conclude that I would LOVE to have a version of DDII that could use the full 24-pin resolution!!! As it is, the character height is a bit off, so pagination doesn't work right, and of course the resolution isn't quite as good as the inherent resolution in the 24-pin printer's internal Letter Quality font.

Maybe what I should really be asking is if anyone has a font editor for 24-pin printers like the Fujitsu or the Epson LQ-1500/2500? The two-pass printing probably isn't really needed, as the logic of the 24-pin printers accomplishes much the same thing in one pass using the finer pin spacing instead of carriage motions.

Then again, I'm probably the only kid on my block with a 24-pin printer on a $70 computer...

An Atari 8-bit GIF viewer is on CompuServe.
I haven't downloaded it yet, though.
If I should happen to download it (I don't have much use for it right now),
I'll try to uuencode it and post it.
I'm assuming that it's public-domain, since it's in their data libraries.
But then again, Antic has files in Compu$erve's data libraries and they're
not PD.

Don't look for me to post it soon, though. As I said above, I don't have a
use for it. Also note the substitution for 'S' in CompuServe a few lines
above :-)

Yes, the cartridges should work on a 1200XL.

Just to make sure there were no problems, we had someone try the three Accolade titles (Hardball, Fight Night, and Ace of Aces) on a genuine 1200XL today, and they all worked.

>
> --Ron fireplace@cup.portal.com "I'm not an actor,
> sun!portal!cup.portal.com!fireplace but I play one on television."

We have tried this and it is as it says VERY fast and much more compressed.
Here are the results we found : First is some timing in minutes and secs:

ARC ALFCRUNCH

TIME TO DECOMPRESS
SCREEN ON 5'50" 1'53"
SCREEN OFF 4'30" 1'50"

TIME TO COMPRESS
SCREEN ON 4'49" 1'47"
SCREEN OFF 3'50" 1'35"

FILESIZE in Sectors
ACTUAL 231 231
COMPRESSED 143 114

==========
ARC12.COM 93 ACRX12.COM 88

DZ.COM 27 LZ.COM 24

After this was tested on the 8 bit, the docs were separated and ALF'd into
its' own file. It was successfully dearc'd with the ST's UNARC.TTP which is
compatible with the latest compression routines found in the PKARC method found
on the IBM and the B version of ARC 5.21 for the ST and IBM. I haven't tried
the ARC 5.21B on my ST but will do so in the next day or so. Maybe we will
have something else to relate. For now it seems possible that the 8 bit
Atari computers now have a FAST compression method which is still compatible
with files available on the other Atari and the IBM machines.

The above results were tested by Bruce Fortier and myself of the NSACUG
which is the Nova Scotia Atari Computer Users group. Bruce did the tests
on his 8 bit and I tested the ALF'd file on my 520ST system.

Isn't it true that Compu$erve specifically states that information on its machines is NOT public domain? After all, if a few persons always post the good stuff from their libraries, no one has the incentive to subscribe.

From what I remember from the older days, Keith Leidbetterc did
make a version of his Express program specifically for the MPP
series modems. The program was called MPP Express, and I had seen
it working, so I do know that it does indeed exist.

BTW. The MPP modems did use the Joystick port for the
communications link to the modem. With a little looking you
may be able to find it. I myself do not have a copy in the
proper format and disk, otherwise i'd send it to you.

THIS IS A PLEA FOR HELP!!!!!

If anybody has ANY infromation on Computer Viruses, Immunizations, etc.,
please forward the infromation.

I am working on a senior project on computer viruses. I would like to try
to write an immunization program, however, I cannot obtain enough information
from published literature to do so.

How do viruses work inside the computer. What are some present methods of
detection? Are there any public domain immunization programs available?
Where? Somebody wrote in one article that one could write a virus using the
pc-dos appendices as reference...I looked this up and was not too successful...
how do I do this?...What was meant by this? What are some infected programs
which were available? What is the SCORES virus? How about VirusX?, etc...

Thank you,

I have an atari 800xl and a rs232 modem which I recently bought.
I am trying to find the *right* communications package to use with
this set-up. In my humble opinion it should be able to emulate a dec
with 80 columns, it should also be able to handle my modem without
me having to write any new handlers. I have been considering the omnicom,
but I would prefer the true 80 column board, atari came out with, if there
is suitable software for it. I dont have much experience with the atari
and in such dont even know how to connect the modem yet.
I would greatly appreciate any help or recomendations.

1342. Pawn for 8 bit Ataris

Newsgroup: comp.sys.atari.8bit
Date: 1988-07-22 18:15:42 UTC
From: Jack_Mason@CSC03.CEO.DG.COM
Message-ID: <36.013261@adam.DG.COM>
Source record: 116746

Re the question on why Pawn is no longer in stock, according to two wholesalers, it has been discontinued. Maybe another letter writing campaign would help?
By the way, this cry by publishers that too much piracy on the Atari is hurting is all relative. There are far more pirates on the Commodore 64, its just that there are far more Commodore 64s, so the publishers still see what they consider decent sales. There are no copy protection schemes that work on the Commodore!!

1343. Alfcrunch vs ARC vs Diskcom

EVALUATION OF ARC, DISK COMM, AND ALFCRUNCH

by

Marty Albert

June 9, 1988

Well, here we go again. Another comparison of file compression systems for the Atari 8-Bit Computers. Frankly, the way things look from here, this may very well be the last such comparison done by me. (what's that? cheering?!?)

This time, I've taken a look at ARC/ARCX 1.2, Disk Comm 3.2, and the new AlfCrunch 1.2 that has just started showing up. I've taken a very close look at them in fact, and I had more than a few surprises!

First, let's see the test data, them my own editorial comments.

Test Setup

All tests were done on the following system:

256K 800XL
1-1050 with US Doubler
1-meg MIO
SpartaDOS 3.2d

All of the source files were on the 1050 and the compacted files were written to the MIO RAM-Disk during creation. For recovery, the compacted files were on the MIO and the recovered files were written to the 1050.

In all cases, the high speed option was enabled.

In all cases, the computer was re-booted to get rid of all excess memory use between each creation and recovery.

Recovery was always to a freshly formatted disk.

The files use as source files were:

SAVEd BASIC ------- 12078 bytes
Binary Load ------- 13054 bytes
Compiled T-BASIC -- 11877 bytes

ASCII Text -------- 8740 bytes
Atari Font -------- 1024 bytes
Virtuoso Show ----- 6528 bytes
MI Picture -------- 7684 bytes
Daisy-Dot Font ---- 2307 bytes
KOALA Picture ----- 1881 bytes
RLE Picture ------- 6550 bytes

TOTAL 71723 bytes

All byte counts were based on the numbers provided by the SpartaDOS 3.2d directory listing.

Times were kept with a stop-watch and are as accurate as possible. Allow a +/- 3 seconds to the times.

On ARC/ARCX and on AlfCrunch, the screen was OFF to speed up the processing. They were also run from a SpartaDOS BATch file and/or the command line input feature.

On Disk Comm, the entire 256K of the 800XL was used.

Test Results

The following chart is the results that I got with the test:

PROGRAM TTM TTR SIZE % CHANGE ERRORS

ARC 7:01 6:07 55630 -22.44% none

AlfCrunch 1:37 0:57 50541 -29.53% none

Disk Comm 3:53 1:36 66416 - 7.40% none

Evaluation of Tests

ARC/ARCX

Well, no big surprise here. ARC is slow, but does a wonderful job of compression. The compression of the files is not really all that big a deal for the local BBS, but for an on-line pay service like GEnie or CompuServe, that can be *very* important! Again, I failed to get the damage to the recovered files that has been so often reported. But, this is all old news.

Disk Comm

Again, nothing much different here, either. Disk Comm is much faster than ARC, but doesn't do much in the way of compaction. For the occasional boot disk, Disk Comm is probably the best way to go, but more on that later in my editorial comments.

AlfCrunch

All I can say is WOW! I've always said to those that don't like ARC that as soon as something better comes along, I'll go for it. Well, here it is! Not only is AlfCrunch faster than ARC/ARCX, it's *faster* than Disk Comm! And, to sort of add insult to injury for Disk Comm, AlfCrunch even compresses *better* than ARC!

After I saw the above results, I went back and used AlfCrunch on many more files, 40 all told, and did not not get a single damaged file. I tried all sorts of files ranging from long BASIC XE programs to tiny little data files. They all worked fine after being processed and recovered.

It looks very good, but again, more on that later.

Editorial Comments

DISCLAIMER

The comments here are my own. They are NOT the official position of anyone or anything except myself, nor should they be read as anything but opinion based on the above tests.

I've always liked ARC. It may be slow, but it's good. Perhaps that's because as a SysOp on GEnie, I'm more aware of the costs in dollars for downloading big files.

I also like Disk Comm. It's easy to use, reliable, and fast. It also does at least a little compaction, which is more than can be said for the other boot disk systems. I've never been happy with the light compaction, though, and I still think that a better way can be had.

So, along comes AlfCrunch. At first, I thought it to be just another cute toy that someone had done. Was I ever wrong! When I ran the tests (by the way, AlfCrunch was the last one I tested), I was shocked by the speed. As you can see, AlfCrunch is far faster than Disk Comm. At that point, I figured that the compression would be light. When I did the directory and saw the byte count, I just knew that SpartaDOS had just shown me some hidden bug. I tried it a few more times, with the same results, and the file recovered into the right number and size of files, and they all worked!

Needless to say, I was blown right out of the water!

Then came the neat part.

My ARCVIEW program works on the AlfCrunched file! I get some garbage characters in there, but it works. I think (not sure!) that this is due to the file header used. That remains to be seen for sure, though.

The bottom line is this:

For boot disks, keep on using Disk Comm. It's the best that we have right now. I'd like to see better, but who knows?

For the files that you've been ARC'ing, have a look at AlfCrunch. As you can see, it seems to be far superior to anything else now available.

One note about AlfCrunch. The DOCs are *very* complete, except that the author's name/address info is skimpy. What shows up in the DOCs is:

Alfred
Programmer's Aid BBS
(416) 465-4182

I'd like to know just who this guy is!

So, Alfred, if you're reading this, let us know who you are!

A lot of people may repeat this or offer different opinions, but in MY opinion, the *very best* DEC-emulating, 80-column program is John Dunning's port of Kermit65 (originally from the -cough- C64, I believe). Advantages are that you can toggle screen display mode between 40 columns (standard Atari GRAPHICS 0) which can "scroll" horizontally to 80 columns, and a software 80-column-emulation mode. Terminal emulation can be VT52, VT100 (the *best* I've used, better than VT10-squared, Omnicom, Chameleon), or "none" (dumb ASCII). Kermit file transfer is supported quite nicely. Dis-advantages: no way to "ASCII capture" a terminal session, "Print screen," or perform other file-transfer protocols besides Kermit. I don't find those to be even minor annoyances, since I never use those features anyway, but Oyou should be fully informed. Other netsters feel free to add to this commentary.

Kermit65 looks for an "R:" device driver, functionally equivalent to Atari's original R: handler for the 850 Interface, but this does not LIMIT YOU to using the 850 Interface. Any driver that LOOKS like the original driver to Kermit65, will work; I've used it with an SX212 modem connected directly to the SIO bus, using the RVERT212 handler, and I've seen references on this net to people using it with an XM301 modem and appropriate handler.

> I dont have much experience with the atari
> and in such dont even know how to connect the modem yet.
> I would greatly appreciate any help or recomendations.

This depends pretty much on what kind of modem you have. If you were to use the Atari SX212 modem, it has an SIO jack and can be connected to the end of your normal peripheral-devices "daisy chain." You'd then have to obtain the RVERT212 handler and load it into memory before loading Kermit65 or whatever terminal program you decide upon. (RVERT212 can either be loaded as a sepa-rate file, or can be prepended to your terminal program to make one BIG file.)

If you have a modem other than the SX212, you will need some sort of hardware interface unit to make the Atari capable of speaking RS232, and vice versa. (In the SX212, this is basically "built in," is all.) Such interfaces include, but are not limited to, the original Atari 850 Interface Module (I use this), the P:/R: Connection (I've helped install one), and a couple of other things whose names escape me -- perhaps you readers can assist!

Good luck on whatever you come up with; once you get it set up it all looks really simple in retrospect!

From: rmrin@inuxh.UUCP
Message-ID: <668@inuxh.UUCP>
Source record: 116752

I recently bought a P-R connection
to use with an AT&T 4000 modem I had
lying around. Unfortunately, when I
fire it up with my brand new 130XE
(new to me anyway, I don't know how
long it's been in the box at the
dealers) I get the diagnostic "turn
on the 850". This also happens sometimes
but not always when I use the machine
with my original 800XL. It appears
the P-R Connection is not talking
to the 130XE politely enough. Can
anyone make a suggestion?
Also, when I went for the 130XE I also
ordered an upgrade of Syncalc as I
understood the later version would use
the expanded memory. Unfortunately, the
new discs show the initial trademark but
will not load the program. Any help
here? Thanks, Dick Rickert AT&T INDY

1350. Re: digitizing...

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-01 19:52:00 UTC
From: PHR140@URIMVS.BITNET
Message-ID: <8808011956.AA13722@ucbvax.berkeley.edu>
Source record: 116754

The only way that I can think of to get the digitized sound
to come out of the tv speaker is to hook a d/a converter up to the
joystick ports (set up the pia for output) and hook the output of the
d/a converter to the audio input on the serial cable (pin 11, I think).
Alternatly, you could try to use the data to drive the amplitude of
one of the sound chanels, if you know the aproximate frequency of the
sound you are tring to digitize. This would only work if the frequency
of the sound does not change much..
I had tried to digitize sound through the pot inputs once before, but
it never worked quite right. Where did you see the article that said
how to do it?? I would be interested in reading it..

I haven't played with sound stuff in awhile, but as I recall, you can output sound using "noise only" through POKEY. When you use noise only, the volume bits determine the position of the TV speaker directly. I'm pretty sure you could play digitized sound this way if it has enough bits of precision for you... Now that I think of it, it's called "volume only." You just have to set a bit in AUDCTL.

Steve Whitney (I have no signature file yet... maybe someday.)

1352. Re: digitizing...

The article was in and old Analog or Antic that my friend had. However, when I wanted to borrow the article from him recently, he could not locate it.
The program that went with the article supposedly let you digitize sounds through a microphone, hooked up to the joystick port, and then allow the sound to be played through the T.V. speaker.
Anyway, how much do 8-bit d/a's go for these days, or would it be more economical to by the Parrot II from Alpha systems?

thanks,
Greg Scribner

Yes, Steve, it CAN be done, and HAS in fact been done. I have several programs on my 800 that play snatches of digitized music through the TV (monitor) speaker: the Kinks' "You Really Got Me" (sic), and Huey Lewis' "Back In Time", to name just two. The resolution is pretty limited (a scale of 0-15), which results in severe audio "clipping" (i.e. non-linearity, i.e. "staticky" or "noisy" sound), but there's no difficulty in identifying what is being played.

I, too, would be interested in a reference to the magazine article that inspired the original poster; i.e. if I can digitize at home with simple electronic components, I'd love to know how!

This is all from the top of my head, but what you are looking for is the volume only bit in the audio control registers. It lets you specify 3(4?) bits of D/A resolution. The A/D converters used with the paddles provide 8 bits of resolution, and their fastest conversion time is 2 scan lines.

Of course, if you don't have "Mapping the Atari", and the Atari Tech Notes, you should get them immediately. De Re Atari is also very worhtwhile.

Good luck. If you need more information, you can reach me at:

From: brett@pigpen
Message-ID: <2966@umd5.umd.edu>
Source record: 116661

I have seen a few messages posted here about some of the old Atari manuals, and if anyone wishes to buy mine, I would be happy to sell them. I use to program on the 800 in assembly language, but I have moved up to a 68000 and only use the 8bitter to play some Lucasfilms games and M.U.L.E.

I have the Technical Notes (Hardware Manual, OS Manual, and OS Source code),
De Re Atari "All About Atari",
Atari Assembly Manuals
Inside Atari DOS which has the source code to DOS 2
along with the last four years of Antic and ANALOG magazines, but I think I will hold on to them, unless someone really wants them.

The prices for this stuff, well, I don't really need it and if it would help someone else, all the better. I guess a small fee for shipping them out and a few dollars would be enough. I am not trying to make money off of this, just trying to let others get some good use out of the manuals, as I did.

From: brett@pigpen
Message-ID: <2967@umd5.umd.edu>
Source record: 116662

I wrote an article for ANALOG a few months back, about a 3D starts program that make a display something like the Star Trek opening scene with stars flying at you. Well, to make a long story short, they said that this type of article would not appeal to a large number of their readers, and sent it back.

What is the policy for posting source code, (it is in assembly language and is very small) and binaries (even smaller 8^)) to the 8 bit net? I would be happy to release it into the public domain and at least let people see it.

BTW - was ANALOG right? Is this a topic which would not interest 8bitters?

In words of one syllable "F*ck 'em." ANALOG obviously has their collective
head inserted in a difficult-to-reach anatomical orifice.

In other words, *I* would like to see it, as will probably every other
"Atarian" in this area. My friend, reading over my shoulder, confirms HIS
agreement...

If you need a 1050 diagnostic disk, you might try American TV (technavision) in california. I know they have all of the manuals, and diagnostic cartriges, but I am not sure about disks. They advertize in both analog and antic. I hope this helps..

I was talking to my friend tonight about that article and managed to come up with the Magizine, year and title. According to his memory it was in a 1984 Antic and the title was "Talk is Cheap".I would appreciate if anyone with access to the 1984 back issues of Antic to post the exact issue in which it appears.

thanks in advance,

Greg Scribner

A friend of mine has built the device you have been
describing and nominally sells it (it was some time ago but
he likely has some units left.) It was called the Vigitizer,
and came complete with software that allowed you to record,
playback, modify the buffer, etc.

Last I knew, mike and all it ws $30. I don't believe they've been
"trying" to sell things in some time but if anyone's interested
I can try and hook you together.

Terry Conklin

My 5-year old son recently got the new 8-bit cartridge Blue Max.
It's a good game for his Atari 800 XL, but he has had trouble
landing it according to the instructions. I also have trouble.
After pressing the joystick button, the plane sometimes can
land and sometimes can't. What's wrong? Thanks in advance.

I believe, Bill, that you must slow all the way down (to 100 mph, is it?)
before the plane will land safely. I.e., you press the joystick button,
the "speed" readout starts dropping, and you can land safely only after
it STOPS dropping and "bottoms out," as it were. Try that.

If my memory serves me right, the plane has to be at a certain altitude when approaching an air strip and then you have to press the fire button to lower your landing gear. Also, I believe it prints out somewhere on the screen that your landing gear is down when the latter procedure is correctly done. Hope this helps.

later,

Greg Scribner

Yes, there *ARE* Centronics interfaces out there, ie. Centronics Parallel, you do not specifically say Parallel, but I assume (no flames for assumption please...) if that is what you mean, here is what I know of for the Atari 8-bit series. I own an 800XL, 1050 Drive, Color monitor etc...

*NOTE: all of these work by being hooked to an Atari computer by using the SIO port via SIO cable.

To list: 850 interface 1 Parallel, 4 RS232. The parallel will hook up to a Centronics printer, I know I *own* both the 850 and an Epson RX-80 Centronics Parallel printer.... The 850 is still available used and *NEW* look in ANTIC and/or Analog (groan...) for the whereabouts of said 850...

Printer Connection, 1 Parallel port for hooking up to a Centronics Parallel printer.

P/R Connection, 1 Parallel, 1 or 4 RS232 ports similiar I have heard to the 850 but I have never seen one.

The 850 is made by Atari, the Printer Connection and P/R Connection are made by ICD Corp. out of Illinois. I was going to buy a P/R connection till I found a place in California that sold 'Like New' 850's for 89.00, have had mine for over 4 months with no problems, and none are forseen... If you want the address of the place I bought my 850 let me know, I can even dig up the address(s) of the places of the other places that sell the P/R and Printer Connection... (B and C Computervisions is where I bought the 850.)

Disclaimer: I do not work for 1)Atari, 2)ICD or 3)B & C, I am just a happy customer of 1 and 3, and am trying to help a fellow Atarian.

>back.

When I first subscribed to ANALOG, way back when, they had very good technical articles of all kinds. Even the games gave you good insight into the workings of the machine, as they always published the source. Writers like Tom Hudson, Brian Moriarty, Kyle Peacock, and others who I cannot think of offhand really gave the magazine a lot of technical depth. When those people left, the people who took over did not seem interested in anything but adventure games, BASIC versions of old board games, and gossip. As a result, I let my subscription lapse about 2 years ago. I have not seen anything in that time to make me regret my decision.

My advice to you is to submit it to ANTIC. I sent ANALOG a Dvorak keyboard handler program about 3 years ago. They rejected it, saying it was "too technical and would not appeal to our readers." I then published it in our local newsletter. Well, it got reprinted in some other newsletters, which flattered me, and then ANTIC saw it and asked me to submit it to them (!). I did, and it got published in April of '87. I'm not saying this to brag, I'm just showing that what might be worthless to some people might be worth enough to others that they will come looking for it.

Of course, given ANTIC's overly-protective redistribution policies, it might be better for us if you posted it. Then again, ANTIC pays better ... :-)

Source record: 116679

I agree, the best known choices are Atari's own 850 interface, usually sold for $109 but apparently available used for $89 if you are lucky, and the ICD P:R:Connection. There's also one called the ApeFace, which is strictly a parallel printer port. The Atari 850 indeed has 4 serial ports as well, and the P:R:Connection has two of them.

I have seen at least one disk drive (the Trak) that has a built-in printer port. I think others (Supra) may also.

For all of these, the built-in P: driver and the LPRINT command in BASIC work perfectly normally. You would not have to mess with writing a custom driver.

Finally, a lot of people have built up their own interface to run a printer off the joystick ports. These are basically the Data lines of a PIA chip, and can be programmed to be outputs, although they are normally set up as the joystick inputs. I haven't seen the details, but the trick will be to derive a strobe line to tell the printer to read the data. It has been done, so if you can think up a scheme or find out how others have done it, you can build an interface with almost no parts in it, i.e. just the logic for the strobe. For this approach, you WILL need to write a driver, and if you do it right, the method should look like a normal P: device to the calling programs, including BASIC, meaning that LPRINT will still work. Of course, you would probably have to unplug the joysticks, or at least provide a switch to select joysticks or printer.

After just reading a second hand copy of "The Art of Computer Game Design, Reflections of a Master Game Designer" by Chris Crawford, I wonder are there any other books of this type out there?

Most of this book was extremely dated to the 1984 video game market. However, a couple of the chapters in the middle were quite informative. Chapter 5, "Design Techniques and Ideals", discusses what Chris Crawford considers critical design principles in designing computer games.

Throughout the book he discusses his greatest software releases. I purchased and play "Eastern Front", but what is this "Excalibur", "Legionnaire" and "Gossip"? Are these titles something I should look for or weren't they worth a look?

As you commented (edited out) about how the book was dated, yes, so are the
games. Excalibur was released not by Atari, but by that same company that
destributed the sequel to Caverns of Mars and Karnov's (wrong name, and no
it's not Pavlov's, it's some canine pun name) Dogs (the company that distributed
Atari games that people wrote but no one else would sell). Gossip was never
finished to my knowlege (and would not have had much of an audience had it been
released) and I've never heard of Legionnaire; though even now that I have I'm
not terribly excited about it.

1378. XF551 Disk drive

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-15 23:25:23 UTC
From: Hugh_E._Wells.ElSegundo@XEROX.COM
Message-ID: <880815-162514-1059@Xerox>
Source record: 116682

8/15/88

Has anyone experienced the XF551 drive going to sleep? I'm aware of two drives that periodically fail to respond to the normal boot process. The SLEEP syndrome is not like the one exhibited by the old 810 drive which went to sleep in the middle of an operation.

These drives are attached to different systems and operated by different people. Once booted, the drives continue to perform normally. Only the start-up boot is in question. The XF551's are attached to 800XL's.

I'm trying to determine the following:

1. Whether the XF551 design has a problem.

2. How frequent does the problem occur?

3. How it can be circumvented, or how to get the drive to respond while it is asleep? Multiple re-boot cycles are usually required for a start when the drive is acting up.

4. Any fixes that may have been developed to correct the problem.

5. Is there a known problem with the 800XL enable voltage level being in the TTL marginal logic voltage band?

6. I would also like to obtain a schematic set for the XF551.

Any information you can provide will be appreciated.

Hugh

Yes,and by Crawford himself. You might want to check out his book called
"Balance of Power" (from Microsoft Press). This is mainly about the
game for the Macintosh and Atari ST,but I found the book interesting about
learning how he designed the game and other "background information".
Crawford has made many games I've enjoyed and I miss them since I don't
have a disk drive anymore.

> Throughout the book he discusses his greatest software releases. I purchased
> and play "Eastern Front", but what is this "Excalibur", "Legionnaire" and

> look?

I also have Easter Front and find that a very enjoyable game. So much so
that after I sold my 8-bit system two years ago (130XE),I got a 600XL just
so I could play that game soon after.

Excalibur is the only game I've played from the list above,and let me say
that it took me over two years to find that one. I finally found it when
Atari was sold to Jack Tramiel when he ran those "Atari Extravaganza" ads
in the Explorer magazine for $9.95. This game is fantastic! I just wish
I could play it! I haven't been able to play it in two years,since all I've
got is that 16K 600. I just waiting for the "right price" when I can get
another 8-bit again.

Excalibur is the most complex game I've seen for the 8-bit Atari. It
comes with a novel to help the user understand the background of the game.
The object is to have you (King Arthur) rule Camelot and keep the peace
while expanding your nation. I wish I could do this game justice with a
better review,but since I haven't played it in over two years,I cannot.
If role playing games are your style,this one's a goodie.

For a sample of the game,here's the different rooms involved with game play:

(from the manual :-})

1) Round Table Room - where each knight is shown and ranked as to loyalty
to see who's on "your side".
2) Throne Room - get news about Britain,Attack another king,or pay a
tribute to a King.
3) Treasury Room - see the levels of Wealth,Tax,Army,Tithes,and average

military experience of your men.
4) Merlin's Room - used to cast spells,and "See" (Merlin puts you in disguise as another King to see their castle as you would see yours- handy to see their strength). Plague,Pestilence (kill the crops of another King), and Change (make another King like you more- only temporarily). Each spell or action makes Merlin weak,and he goes away for a while to recooperate.
5) Trap Room - You are put here when another King attacks you-has the info you need to fight.
6) Britain (map of Kingdoms) - Battle Kings,see other territories,and place spells here.
7) Battle - Much like Eastern Front.

The graphics were the best I'd seen for the 8-bit (Old English text too),and I don't think they've been topped yet (overall- not just a good title screen). The game reminded me of the movie of the same name,which I also liked. Good luck in finding this one!

BTW,It was originally published by the Atari Program Exchange (APX).
Remember them??

1380. Atari 8 bit A to D request by Greg Scribner

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-16 14:36:03 UTC
From: Drbob.WBST139@XEROX.COM
Message-ID: <880816-141440-2966@Xerox>
Source record: 116684

Greg:

The digitizing sound article appeared in the July 1983 issue (Vol. 4, No.2) of ANTIC. The author was Ed. Stewart, and the title was "Talk Is Cheap". Also in that issue was a second article by Ed. Stewart titled "Hokey Pokey Interrupts" --- another useful article. Unfortunately, in true vintage ANTIC style, the program listing for the audio digitizing article somehow got lost and was belatedly printed in the August 1983 issue of ANTIC!

Bye the bye, if you want to fiddle with an external A to D chip, then a simple low-cost option is the Texas Instrument TLC548, sold by Radio Shack for $3.99 (sale price) under their catalog no. 276-1796. This chip needs three lines from the controller port (to trigger the chip, to clock the data out, and a data out line for the serial output), plus 5 volts and ground, also stolen from the controller port. For SLLOWW conversions, you can control the chip from BASIC; for fast conversions, you'll need to write a short assembly routine.

Sounds like an interesting read. I read a magazine article describing the creation of "Eastern Front: 1941" and found it fascinating. It was in one of the "standard" computer magazines like _Antic_ or _Creative_Computing_.

>Throughout the book he discusses his greatest software releases. I purchased
>and play "Eastern Front", but what is this "Excalibur", "Legionnaire" and
>"Gossip"? Are these titles something I should look for or weren't they worth
> a

I purchased "Legionnaire" on a cassette released by "Avalon Hill, Microcomputer Games Division" and transferred it to disk quite easily. I like the game, but not as much as I like "Eastern Front". The mechanics are similar, but "Legionnaire" requires more arcade skill. The enemy keeps moving as you enter your commands. Although the colours are a bit drab, the graphics are quite impressive. Definitely worth a look.

In responce to my posting about my 3d Stars Demo and the manuals I have that I was willing to give away... I have received all your requests and the encouragement from email messages and will post the source AS SOON as I visit my old home in New York and pick it up. I do not have the source here, but on Tuesday I will be back and will type it in my UNIX machine.

The same goes for the manuals; I have all the requests and will send them to these people. I am sorry I could not respond to each person but I have been real busy here. The first person to request each of the manuals will get it. All I ask is that you send me whatever price the postage says on the package. I am not requesting any other money, (as Matt Dillion would say, "I'm not a starving artist.") but would dumb if I didn't accept some if it was offered. 8^)

BTW I will not be able to post the binaries because I do not have my 8 bit here in Maryland, and I have away my 850 interface and modem, so I can't transfer it. Maybe when I post it, someone who has a modem on their Atari could compile it and then post it to the net? (Just please don't change it and THEN post it.)

Again, sorry for the delay and will have the source posted as soon as it is on my machine. Thanks for waiting.

- Brett

I would like to know if anyone else here has built the WeFax decoder that was featured in Antic a couple of years back. I built one and it does work. It is designed to only plot in B&W but I would like to modify it to distinguish for the shades of grey. It would be nice if I could also modify the prg. It is written in Assembler (Mac 65) but I don't know any.

If anyone has built the device or knows where to find fax downlinks please contact me.

Gene Merritt

1384. Relocatable file format?

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-18 23:17:41 UTC
From: hoser@ucrmath.UUCP
Message-ID: <387@ucrmath.UUCP>
Source record: 116688

In the ICD product catalog (88-89) the SpartaDOS X cartridge states that the "file loader supports relocatable files and symbolic linking". What is the format of the relocatable files which this loader supports? I want to write a macro assembler/linker and I would like its relocatable files to conform to whatever the "standard" format is on the Atari 8-bit for relocatable files. I had already considered an object file format for use with a linker, but it would be a better if I could use some sort of standard format which would be able to take advantage of file loader of SpartaDOS X. If there isn't a standard, what is the format of the files that ICD is supporting? Am I misinterpretting what ICD means by "relocatable files and symbolic linking"?

Any information would be appreciated.

I think you're going to find that this is an in-house or "de facto," rather
than "official," standard. There is NO "official" relocatable file format;
Atari never supported or implemented any such thing, so it's pretty likely
just ICD's brainchild.

Someone else on this net (was it John Dunning, of Kermit65 fame? Forgive me
if it was someone else) mentioned to me a couple of months ago that he was
trying to implement something along the lines of your idea: an assembler and
linker etc. to use, support, and manipulate relocatable code and files. All
in all, I'll be glad to see it, but it sounds to me like it's going to be
difficult, because of the 6502's lack of any PC offset register. The idea of
relocatable code descended from mainframes and met the microprocessor indus-
try on its way up, so the "high end" micro CPUs can do this "no sweat." On
the 6502, you'll have to relocate the code and resolve all address references
down to absolutes before ever giving control to the loaded code... Like I
said, I'll be impressed and GLAD to see this when it's ready!

Hope this helps.

Speaking of Kermit-65, what is the latest version, and is the latest version available on either GEnie or CIS?

I currently use Chameleon, since it does handle Xmodem. Unfortunately, due to a bug/shortcoming of it, there's a nasty problem when I attempt to go to the 'disk utilities' section, such as to get a directory, and it locks up. This is most likely since I am using SpartaDOS, and Chameleon is somewhat old, at least I can still transfer onto my ramdisk. I had a copy of Kermit-65 that didn't work too well, that was awhile ago, but even though it lacks xmodem (the system I'm on ONLY supports xmodem, no kermit), still would be nice to have.

I'm also <very slowly due to lack of free time> working on a modular term. program. Currently supports the 80 column simulation on the 40 column screen as Kermit-65 and Chameleon, hopefully I'll be able to get some transfer routines done soon and get the vt100 emulation back in. (Had Vt100 until I took it out when I made the translation mode modular.)

[Would anyone out there happen to have a 'flowchart' or even some Action source code for xmodem/xmodem 1k operations? I have a description of it all, but it's a bit difficult to follow.]

It is my understanding that the old 800 has 8K of RAM which is somehow switched out when a cartridge (esp. the BASIC cartridge) is installed. Is there any way to get temporary access to that RAM while the cartridge is plugged in? I have a 65XE, and am aware of how it is done in XL/XE; I am writing an application which uses this feature, and would like very much to make it compatible with the older machine.

Source record: 116695

After hearing so much on how to do 3D on the Atari 8-bits, and being thoroughly convinced that it (3D) can be done on such an awesome (for it's day) computer, I went to my nearest Kay-Bee toy store and checked out the Sega LCD glasses. Has anyone else dared to look at the hardware?!?
I was a little shocked to find that the glasses terminated in what everyone knows as a headphone plug. Humm...where's the 9 pin female connector?
Well luckily, also included in the box, there was a gadget that plugs into the Sega ROM card slot (the ones the size of credit cards or so) and into the gadget plugs the glasses. It seems that not only do we have to write 3D code (of course we would have had to do that anyway...), but we must also have to build a hardware hack to use the (cheap?) Sega LCD glasses. We'd probably be better off if the people who make the ST's 3D glasses lowered their prices or came out with an 8-bit version; at least we know they would be semi-compatable to compatible w/o a hardware hack. I'm in the process of trying to obtain specifications on the glasses. Whether or not Sega just hands that stuff out to interested parties is yet to be known (that's why I'm 'in the process'). If I hear from them I'll post a summary of what they say.

Sincerely

If a cartridge is plugged into an 8-bit Atari, it is not normally possible to access the RAM underneath. The built-in BASIC ROMs can be switched out with the PORTB register at $D301. OSS "SuperCartridges" can also be switched out, although I don't know the method for doing so. If the cart has no provisions for being disabled (e.g. the BASIC carts for the 400/800), then they simply cannot be disabled, and the RAM beneath them is unusable.

From: conklin@eecae.UUCP
Message-ID: <11045@eecae.UUCP>
Source record: 116698

I have an XF551 (which I am very pleased with, folks. When you get used to IBM / TRS drive quality) and it has exhibited a similar behavior.

Using SpartaDOS to create a double-sided disk, I have noted thatyou have to "teach" the XF551 to recognize double-sided mode after it's been turned on. When you first power the drive on, it will not recognize double-sided boot disks. If you boot under the appropriate dos, however, and then READ from a double-sided disk, the drive "realizes" that it's double-sided. You can then turn off the computer, disconnect lines, etc. and still be able to boot from DSDD disks.

My solution? My XF551 has been on now for oh, a month or two? That's ok, my TRS Mod I that runs the Club BBS has been on 8 -years-!

Still, I find this distressing. It may have been on purpose, however, as some mutant software perhaps was found checking for a double sided drive?

A little news from Atari Eng. group on this would be appreciated.

That is correct.

> Is there any way to get temporary access to that RAM while the cartridge
> is plugged in?

From what I've been able to tell in the six years I've owned my 800, there's NO provision in the system design for accessing the RAM at "cartridge addresses" while the cartridge is present. Unlike the XL/XE, in which a controlling data register is accessible to the CPU, on the 800 this is electrically hard-wired: plugging the cartridge in physically de-selects RAM in favor of cart-ridge ROM. I would think that in order to do anything about this, you'd have to make hardware modifications to the 800 design, giving the CPU control over the RAM/ROM switchover process -- i.e., the very thing done by Atari when they created the XL/XE line based on the 800.

If anyone has counter-proof of this information, I for one would be very in-terested to hear about it. Would indeed be a useful capability. By the way, just what CAN one do on the XL? I just got one to replace my 800, and would love to know what "new tricks" this ol' dog can learn! :-)

Depends on HOW MUCH you intend to ask for! :-) With all the smileys floating around this article, I'll just say "if you get one or two (or more) of 'em built for a reasonable price (you tell ME the price, I'll tell YOU if I think it's reasonable) I'd probably be interested. Now, where in the world am I going to find a set of Sega glasses??

>"teach" the XF551 to recognize double-sided mode after it's been turned on.

I don't think I have had this problem, but perhaps a similar one. I use SpartaDOS so I can use the XF551 in DSDD mode. I find that when I first turn [my 65XE] on, it attempts to boot, and after a few seconds it stops. Then I press RESET and it usually boots OK. Sometimes it just goes into BASIC though and I have to repeat the process. Do I just have something set up wrong?

Also - Atari in 3D! I have seen the Sega 3D glasses (for anyone who doesn't know, they use a liquid crystal shutter on each eye, that alternately open and close to allow each eye to see only those frames intended for it. The effect really does work, and rather well!) available at toy stores like KayBee and Toys R Us for $60. Do you think people would be willing to pay say $25 for a widget to connect them to the Atari, if it included a full set of instructions to programming them? I might also do a set of utilities to set up the display lists and VBI stuff, and do point, vector, and surface graphics in 3D.

Number 3. Has anyone attempted to connect a Commodore mouse to the Atari? I use the Atari trak-ball for this purpose, but it seems a mouse might be better.

Number 4. Back to Sega. Suppose my widget had an orifice for connecting the Sega lightgun to the Atari, doing the rewiring internally. I assume it would be programmed using the light pen facilities already in the Atari. How many lines does the light pen use? I ask because I need one of the port wires to control the glasses.

Fun, fun! -Stan

for some reason, and I don't know how to 'kill' something after its
posted.
.
> From lackey@Alliant.COM (Stan Lackey)
>It is my understanding that the old 800 has 8K of RAM which is somehow
>switched out when a cartridge (esp. the BASIC cartridge) is installed.
>Is there any way to get temporary access to that RAM while the cartridge
>is plugged in?
.
I don't have my manuals in front of me, but basically the answer is no.
The standard 800 has four slots one, the slot closest to the back of the
800 is for the operating system rom. The other three slots allowed 3-16
ram carts to be inserted, giving the 800 its 48k ram complement.
The operating system rom occupied 10k, plus 2k of ram and about 4k
of the address space unused (and unuseable by Atari hardware anyway.)
from about C000 to CFFF. The left cartridge slot (where BASIC e.t.c
would go), disabled RAM from A000 to BFFF if I remember correctly.
The right cartridge slot (if used) disabled ram from 8000 to 9FFF.
The ram was actually disabled by the insertion of the cartridge so
that the rom cartridges could use this address space.
A company named Axlon came out with a scheme originally for the
Apple I believe and then for the Atari 800 to allow bank selection.
A 16k page from 6000-7FFF I think was bank selectable by writing
a number 0 for page 0, 1 for page 1, ----, 7, for page 7. Your
program wrote this number anywhere in the C000-CFFF range (which
as I said before was unused by the Atari O/S or hardware up to now).
Anyway 8 pages times 16k per page gave the old 800 128K of additional
memory which was used by most programs as a ramdisk. This bank
switching technique was later used by the xe/xl line to allow a
full 64k of ram to be addressed although the address used to effect
the switch has changed to an address that used to be one of the
four joystick ports on the 800. Programs which make use of the
Axlon technique do not work on the XL/XE, and programs which work
on the XL/XE technique do not work with the Axlon. Axlon was first
(for the Atari) and its a shame that Atari took a different (and
incompatible) tack later on. I found Axlon to be a very good
company producing an excellent product, when I ran into problems
writing a DOS to use the Axlon board, they sent me printed source
listings for the 'hooks' that they put into DOS 2.0 and the code
to handle the bank switching and disk emulation. Needles to say
that solved all of the problems that I had encountered.
Anyway, I hope this answers your question.

My solution? I put a DS disk (formatted w/SpartaDOS) in the drive, then
turn on the computer. I get greeted with the familer "No Dos" message,
then turn off the computer and on again (leaving the drive on) and it boots
up fine. Seems it "learns" about the DS on its first spin up.

No problems otherwise, and it works great with my ST too (and matches the
case!)

|> boot from DSDD disks.
|
|
| My solution? I put a DS disk (formatted w/SpartaDOS) in the drive, then
| turn on the computer. I get greeted with the familer "No Dos" message,
| then turn off the computer and on again (leaving the drive on) and it boots
| up fine. Seems it "learns" about the DS on its first spin up.
|
I believe that the same thing can be accomplished by merely pressing the
reset key on the XL/XE computers. That may not work for the 800 models
though as the reset is handled slightly different.

1403. NEW NEWSGROUP PROPOSED: rec.games.pc

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-25 20:15:32 UTC
From: jennifer@jato.Jpl.Nasa.Gov
Message-ID: <80@jato.Jpl.Nasa.Gov>
Source record: 116557
Cross-posted to: rec.games.misc,rec.games.chess,rec.games.bridge,rec.games.video,comp.sys.amiga,comp.sys.atari.8bit,comp.sys.ibm.pc,comp.sys.mac

I am proposing a new news group, rec.games.pc for the discussion and exchange of personal computer (not video/cartridge or games available on UNIX/VMS systems) game clues and help. This would include Infocom games, Computer Roleplaying games, graphic adventure games, and any other games available solely for the personal computers. I would also post PC game vendor support messages when I had information pertaining to that. Currently, this discussion goes on in rec.games.misc and various other system based groups. Most games for the personal computers are now ported to most systems, and having a central newsgroup in order to support these games makes sense. This would also allow rec.games.misc to be what it says; namely a group to discuss games that are not covered by other groups, instead of the default repository for PC based games.

This would be an unmoderated group. I would request that when messages contain spoilers, that the word "spoiler" be contained in the subject. When the message contains spoilers that could be based on the actual version of the game, that the version (IBM, Apple, etc) be put in the message.

Please vote by E-mail to the addresses listed in the signature file below. DO NOT POST YOUR VOTES! In order to succeed, there needs to be 100 more yes votes than no votes. The voting can begin today, and end on 9/24/88. I'm directing follow up discussion to rec.games.misc and news.groups.

>someone out there has a 810 disk drive that they would like to sell or
>would like to repair mine, please email me direct.

> Thanks
>
> davidp@tc.fluke.com

Hi David,

Look for American TV (old name) and B&C in the pages of Antic and Analog. Parts and service are available for the 810 drive. Upgrading the boards will make the old 810 as stable as the later 1050 drive. Hopefully, the mechanism is functioning, or is repairable, as new 810 mechanisms are very scarce.

Good luck,

Hugh

1405. Relocatable Object Code Format

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-26 02:30:49 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8808260230.AA10807@mitre-bedford.ARPA>
Source record: 116559

Yes, I think it IS John Dunning who is hoping to "whomp up" a relocatable format and linking loader.

In my opinion, it is PRECISELY BECAUSE the 6502 has very poor support for relocatability that a relocatable object code format and a linking, relocating loader ARE NEEDED.

With such facilities, code can be relocated to the absolute load addresses during the linkage process, all under the automatic control of the linker. Linking will require a little computation, and the relocatable format will be a little more "bulky" than the final, absolute load modules that result. However, once such machinery is in hand, it will become practical to build REAL languages for the 8-bitters. Heck, even a version of ACTION! with the capability of building relocatable object libraries would be a terrific advance! For that matter, relocatable assembly language libraries would be pretty neat too.

I'd be interested in reading a "product review" of ICD's format.

To connect the 3D glasses to an atari should be no problem. All that would be needed is a joystick cable and a stereo jack. Connect 3 wires (2 output lines and a ground), then set up porta to have 2 outpur lines. But now is when the fun begins.. You will need more than just this to see in 3d. You will need to create TWO screens, and a DLI that will flip between them. It would also have to keep track of which eye is can see the screen and keep this in line with which screen is being shown.. This means that now you've got to dedicate 16K to the screen..

About the XF551 drive.. does this ADOS thing exist, or is atari still shipping dos2.5 with it?? One question I have about this drive is what will it do if you put a older double sided (cut the notch type) disk in it?? If you try to write to the disk, will it think it is ok to write to the back of the disk,or think the whole back side is bad (because the data is comming off the disk backwards..)?? Also I remember atari saying that the i/o speed of this drive is faster (2.9x) than the older drives. Does this work in the sam way as the us doubler? (I have 2 usd 1050's) what is the best dos to use with th xf551??

Thanks to Wayne Wilcox for reminding me about Six Forks, which sells an assembler with relocatable object format output and a linking loader to go with it.

Sorry I couldn't reply directly, Wayne, as the return address my mailer figured out resulted in an "unknown host" mailer error message. Anyway, others may want to know about Six Forks, and I want to know if their assembler now supports macros, which as I recall the original release did not.

Anybody know about this?

> to whatever the "standard" format is on the Atari 8-bit for relocatable files.

I think you're going to find that this is an in-house or "de facto," rather
than "official," standard. There is NO "official" relocatable file format;
Atari never supported or implemented any such thing, so it's pretty likely
just ICD's brainchild.

I believe that's true.

Someone else on this net (was it John Dunning, of Kermit65 fame? Forgive me
if it was someone else) mentioned to me a couple of months ago that he was
trying to implement something along the lines of your idea: an assembler and
linker etc. to use, support, and manipulate relocatable code and files. All
in all, I'll be glad to see it, but it sounds to me like it's going to be
difficult, because of the 6502's lack of any PC offset register.

Also true, but misses the point slightly. The kind of relocatable code
I'm talking about is not code where you could pick 'those bytes there'
up and plunk them down someplace else and have them still run. You
could do that, probably by adopting a convention about using someplace
in page 0 as a base register, but it'd be gross.
The idea of
relocatable code descended from mainframes and met the microprocessor indus-
try on its way up, so the "high end" micro CPUs can do this "no sweat." On
the 6502, you'll have to relocate the code and resolve all address references
down to absolutes before ever giving control to the loaded code...

Exactly. In fact, this sort of paradigm is used all over the place.
(See the executable format for the Atari ST) It turns out that you can
make the loader pretty simple and fast if you pick the right format for
describing the relocation info. That's tricky on the 8-bitters, because
the word length is not the same as the length of a pointer. That means
that you end up trying to generate a byte in memory that's (for
instance) the high half of the address of a symbol AFTER it's been
relocated. Blech.

What I have in mind is not quite that ambitious. I'm building an
assembler that generates relocatable object modules, (those of you
who've hacked on ancient Xerox mainframes will notice my terminology

showing thru) and a linker that links the object modules together into a non-relocatable executable image. That's a much more manageable project, I think, 'cause it removes the requirement that the code itself be relocatable, but preserves the ability to run the code at any given place in memory; all you need do is re-link with different base address.

Like I
said, I'll be impressed and GLAD to see this when it's ready!

It's coming; just taking its time. (Despite my blithe statements, it really is tricky to get right) Besides, I've had to take time off from it to spend on my REAL job :-}

1410. Relocatable Object Code Format

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-28 16:01:00 UTC

From: jhs@mitre-bedford.ARPA

Yes, I think it IS John Dunning who is hoping to "whomp up" a relocatable format and linking loader.

Yup, that's me. I've heard of other relocatable object formats, but have never succeeded in getting hold of specs on any of them, and don't know of anyone else who claims to be working on them.

In my opinion, it is PRECISELY BECAUSE the 6502 has very poor support for relocatability that a relocatable object code format and a linking, relocating loader ARE NEEDED.

Precisely. If it was easy to get that functionality, nobody would be worried about it.

With such facilities, code can be relocated to the absolute load addresses during the linkage process, all under the automatic control of the linker. Linking will require a little computation, and the relocatable format will be a little more "bulky" than the final, absolute load modules that result. However, once such machinery is in hand, it will become practical to build REAL languages for the 8-bitters.

Yup, that's my thinking exactly.
Heck, even a version of ACTION! with the capability of building relocatable object libraries would be a terrific advance! For that matter, relocatable assembly language libraries would be pretty neat too.

Yup. In other mail I mentioned my plan to build a linker for the object format I'm working on. The obvious extension is to arrange it so that it can extract modules from libraries, and I've left room in my format definitions for that sort of thing.

I'd be interested in reading a "product review" of ICD's format.

Me too.

Liquid crystals like they use in the glasses are clear with no voltage applied, and go opaque when +-10V at 400 Hertz is applied. There is no way to get this directly from the Atari; a little box with a voltage source, a 400Hz source and high voltage (well, >5V) switcher is needed. The SEGA uses a clever scheme that only requires +10V is used, by putting the square wave on the common and twiddling the phase. Another problem-- many liquid crystals suffer long term deterioration if there is any DC component put across them.

> About the XF551 drive.. does this ADOS thing exist, or is atari
>still shipping dos2.5 with it??
I got mine in late spring. 2.5 came with it, with no mention of its capabilities past the 1050. Except on the box. SpartaDOS is capable of using it, though; this works with Atari BASIC and stuff like that, but the Atari assembler doesn't work under it, and I don't know how to use Turbo Basic under it. OK, so you copy the files to an Atari-formatted disk then reboot and use the other tools. Inconvenient but usable.

>One question I have about this drive
>is what will it do if you put a older double sided (cut the notch type)
>disk in it??
The drive reads the style of the formatting, then behaves exactly like an 810 or 1050. There is no way to tell it to use the back side, short of turning the disk over.

>I remember atari saying that the i/o speed of this drive is faster (2.9x)
>than the older drives. Does this work in the sam way as the us doubler?
>(I have 2 usd 1050's) what is the best dos to use with th xf551??
In 1050 or 810 mode, the drive seems a little faster. To get the higher speed, it really needs to be in DD mode.

Source record: 116567

I know that a month or so ago someone on this list said that an Atari 8-bit virus would be difficult to write, but I just read in the latest issue of Atari Explorer that one exists. Unfortunately, the article didn't go into much detail. I don't remember who the author of the article was, and I don't have the magazine handy. Does anyone know anything about this virus? I haven't had time to check CompuServe yet, and I haven't found anything on Virus-L@LehiIBM1 (though they seem to be mostly into Macs and IBMs, and I've been away for a month and haven't had time to pick up quite all the archives yet).

Jim Shaffer, Jr. -- formerly (and perhaps again) shafferj@bknlvms, now james_shaffer@bucknell

Six Forks Assembler and Linker

I bought this package back in January from Six Forks Software for $39.00. There is an excellent review of the package in the March 1987 issue of Analog and in addition to this review here are a more few words.

The package comes with two programs the assembler, linker, and a sample program.The assembler generates a relocatable code that is used as input to the linker and the linker combines all relocatable files into an Atari loadable object file. The assembler expects a text file as input, this file can be generated using a word processor like ATARIWRITER and Textpro.

The assembler and linker are intended to be used as AUTORUN.SYS files on separate disks. Also they only used D1:, there is no ability for the user to specify a different disk drive. I use them under SPARTA DOS, I put them on my ramdisk for fast access and keep all my files on D1:. One problem I have with this is that the assembler and linker do not have a return to DOS you must hit reset to return which works fine and does not cause a reboot. You do lose your place if you were in a subdirectory on D1:, which is a nuisance.

The assembler does not support macros, it does support local labels and global labels. There is also a bug, if you use the LSR instruction and leave the A operand off, "LSR A", the program will hang.

It has excellent documentation, 52 page spiral bound instruction manual. The manual does not address programming in 6502 assembly code only the operation and use of the assembler and linker.

1416. In search of Jim Shaffer

Newsgroup: comp.sys.atari.8bit
Date: 1988-08-30 21:45:00 UTC
From: jrd@STONY-BROOK.SCRC.Symbolics.COM
Message-ID: <19880830214537.7.JRD@MOA.SCRC.Symbolics.COM>
Source record: 116570

Hello, Jim Shaffer @ Bucknell, are you out there? I've been trying to reply to you about the Atari 8-bit program archives, but the BITNET mail bridges keep bouncing my mail. If you see this, could you try sending mail to me again?

1417. Mandelbrot on Atari

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-01 15:18:21 UTC
From: lackey@Alliant.COM
Message-ID: <2326@alliant.Alliant.COM>
Source record: 116571

A co-worker recently implemented Mandelbrot on a system at work, and I was impressed with the results. So I figured, why not try it on my you-know-what. I was very pleased with the results, never expecting such a tiny program to create such a nice display.

For any neo's out there, the algorithm is to test the magnitude of imaginary numbers as they are repeatedly squared (sort of) and plot a color depending on the number of times the number was squared before its magnitude exceeded the value 2. (Numbers that will never exceed a magnitude of 2 are numbers in the "Mandelbrot Set".) This program simply uses gr.11 which has 16 colors. The color selected by the algorithm is the color selected to plot. If the point has exceeded 15 squarings and has still not exceeded the limit, it is assumed in the Mandelbrot set and drawn as black. This is, of course, an approximation.

There are no bells and whistles (add them yourself!) but here goes.
In BASIC, of course!

```
10 REM MANDELBROT PATTERNS
20 RS=1/40 : IS=RS/4 : REM INCREMENTS FOR REAL AND IMAGINARY AXES
30 ORGR=1.5 : ORGI = 0.6 : REM DEFINES WHERE IN THE COMPLEX PLANE TO PLOT
100 GRAPHICS 11
200 FOR S=0 TO 79
205 R=S*RS-ORGR : REM SCALE HORIZ (REAL) AXIS
210 FOR T=0 TO 191
215 I=T*IS-ORGI : REM SCALE VERT (IMAGINARY) AXIS
220 C=1 : REM INITIALIZE
225 COLOR 1 : PLOT S,T : REM JUST TO SHOW WHERE CURRENT POINT IS
230 R1=R : I1=I : REM LOCALS FOR ITERATIVE CALCULATIONS
235 IF ABS(R1)<1.0E-49 THEN R1=0 : REM STUPID ATARI TAKES UNDERFLOW TRAPS
236 IF ABS(I1)<1.0E-49 THEN I1=0
239 R12=R1*R1 : I12=I1*I1 : REM SQUARE REAL&IMAG PARTS
240 IF R12+I12>4 THEN 300 : REM CHECK MAGNITUDE. COMPARE TO 4 TO AVOID SQRT
250 R2=R12-I12+R : I2=2*R1*I1+I : REM SQUARE AND ADD IN ORIG VALUE
260 C=C+1 : IF C>15 THEN C=0 : GOTO 300 : COUNT INTERATIONS, TEST TERM VALUE
270 R1=R2 : I1=I2
280 GOTO 235
300 COLOR C
305 PLOT S,T
310 NEXT T
320 NEXT S
400 GOTO 400
```

Under Turbo, it takes approx. 1 hour to render a screen.

The values RS, ORGR and ORGI scale the drawing and select origin coordinates.
The values in the program draw most if the Mandelbrot set, but is very slow
because of all the black. Some other values:

RS ORGR ORGI Picture
1/10 2.5 2.4 Small version of the full set, centered on the screen
1/20 2.5 1.2 Larger version of the set
1/40 1.5 0.6 Full screen of the set, with a little offscreen
1/60 1.4 0.5 Close-up of the upper left corner of the set*

* Make sure you do this one!

Try it! You will be impressed.

Possible bells, whistles, etc.:
1) Save/restore pictures to disk
2) Select and area to blow up, using paddle or joystick
3) "Quick draw" at lower resolution to preview patterns
4) Calculate all 4 points in a gr.11 pixel, and average the result

Another thing you may want to know - The patterns get more interesting at
higher resolution (smaller and smaller values of RS). As far as I know,
more and more detail can be seen at arbitrarily small values.

Have fun! -Stan

1418. XF551 Disk drive

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-04 19:26:22 UTC
From: ken@hpclkms.HP.COM
Message-ID: <1270002@hpclkms.HP.COM>

>Number 4. Back to Sega. Suppose my widget had an orifice for connecting
>the Sega lightgun to the Atari, doing the rewiring internally. I assume
>it would be programmed using the light pen facilities already in the Atari.
>How many lines does the light pen use? I ask because I need one of the port
>wires to control the glasses.
>
>Fun, fun! -Stan

Allow me to quote from the Atari Tech Ref.

"When any one of the joystick trigger lines (pin 6) is pulled low, the
ANTIC chip takes the current VCOUNT value and stores it in PENV. The
horizontal color clock value (0-227 decimal) is stored in PENH. The least
significant bit is inaccurate and should be ignored. Since there are a
number of delays involved in displaying the data and changing the light
pen register, each system must be calibrated. Software which uses the
light pen should contain a user-interactive calibration routine. For
example, the user could point the light pen at a crosshair in the center
of the screen and the program could compute the required horizontal offset.
PENH will wrap around from 227 to 0 near the right hand edge of a standard
width display because of the delay. The pen will not work if it is pointed at a
black area of the screen, since the electron beam is turned off. It is
a good idea to read two (or more) values and average them, since the user
will probably not hold the pen perfectly steady."

End of quote. Now, for your enjoyment pleasure, I shall add some (probably
obvious) commentary.

In addition to using the trigger line, the gun will also need to use the
power and ground lines. There is some limit on the current draw from the
joystick, but I can't seem to find it right now. Just exercise caution
as you hook up more things to one port. If you really need to now, send
me e-mail, and I will try to locate the info.

Of course, someone will need to know what locations PENV and PENH and VCOUNT
and their shadows live in, so here is the list.

NAME LOCATION SHADOW
---- -------- ------
PENH $D40C $234
PENV $D40D $235
VCOUNT $D40B N/A

Good luck with the project, and let us know how it turns out. I don't have
time to do the project myself, or I would give it a shot.

1421. XF551 drive & bootup

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-05 04:42:15 UTC
From: Charles_Ordania_Hughes@cup.portal.com
Message-ID: <8786@cup.portal.com>
Source record: 116575

I am not including any of the previous messages but I will summarize the one I am refering to.
There was a question about why the XF551 would not boot up immediately from a double sided boot disk. This problem also occurs on single sided double density disks.
The reason for the problem is because Atari wrote the OS (yep, that means operating system) for the drive and told it that everytime it powers on it should pretend that it is an 810. When you power on your computer and it attempts to boot, it thinks it is looking at a single density disk. The computer then recieves an error when it tries to read the disk. This error always occurs with Spartados, I haven't tested it with a different dos but I suspect it would happen then also.
As soon as the drive encounters the error, it reconfigures itself to the correct density. Then when you hit RESET or turn your computer off and then back on again, the drive is properly configured.
If the problem only occurs with Spartados then perhaps ICD will correct it by forcing the boot program to configure the drive correctly. If the problem is with the drive not doing an autoconfigure than all DOS's will have to be modified to boot correctly.

B-)

P.S. Sorry, no cute sign-off yet...I just got my account back up.

1423. Status on rec.games.pc proposal

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-06 23:24:24 UTC
From: jennifer@jato.Jpl.Nasa.Gov
Message-ID: <131@jato.Jpl.Nasa.Gov>
Source record: 116577
Cross-posted to: news.groups,comp.sys.atari.8bit,comp.sys.amiga,comp.sys.atari.st

By popular demand, I've changed the name of the proposed group to rec.games.micro. This should make it clear what the purpose of the newsgroup is, without implying that the group is for the IBM PC family only.

I'd like to address some of the comments that have been made regarding the newsgroup. First of all, there has been the comment that rec.games.misc is sufficient for handling the traffic in microcomputer game help. I agree with this, but the problem is that everyone doesn't seem to know that that is where they should post help messages for microcomputer games. Therefore, they post in the .sys groups, or occasionally rec.games.frp or other groups. If there was such a group as rec.games.micro then it would be clear where the messages were to be posted. I do not propose that the rec.games.micro group include games originally programmed for UNIX/VAX systems, since there are already several newsgroups (rec.games.rogue, rec.games.hack, rec.games.moria) that support those games. Rec.games.misc can now be a repository for games that don't have their own newsgroup such as Omega or Phantasia or Xword.

There has also been the comment that this group won't cut down on net traffic. I believe it will cut down on net traffic because there won't be the same messages about the same games throughout the .sys groups. Most microcomputer games have been converted to more than one system, and therefore the same messages about these games can (and do) appear in more than one .sys group. A clear example of that is Bard's Tale. There is an advantage to the person playing these games also, in that if he's playing a game that is a later conversion from the original, then in rec.games.micro, he can probably find someone who's played on a different computer but who's finished the game. The advantage to the people reading the .sys groups is that they don't have their group cluttered with game messages that should really go into the rec area.

There was a comment about moderation--if someone wants to moderate this group, fine. _I_ can't moderate it, and really, I don't see the group as having too much "noise" so I don't think moderation is necessary. The only thing I can see moderation doing is to prevent the requesting of copyright information, and currently rec.games.misc readers don't do much of that.

Now for the current vote tally-73 YES 15 NO. I will post another
tally in two weeks.

1424. Daisy Dot II

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-07 02:25:44 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8809070225.AA03445@mitre-bedford.ARPA>
Source record: 116578

Daisy Dot II is available by sending $10 to:

Roy Goldman
2440 S. Jasmine
Denver, Colorado 80222

If you own a standard 9-pin printer such as an Epson, you'll love it.
I tried it on my 24-pin printer and would LOVE to have a 24-pin version,
but the present 9-pin version isn't much use to me at present. If anybody
knows about any plans to develop a 24-pin version, I'd love to hear about it.
Without hesitating, I would send in $24 (or $23, or whatever) for my copy
of a 24-pin version with font editor.

-John Sangster, jhs@mitre-bedford.arpa

1425. Undigestifying messages

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-08 04:18:00 UTC
From: SHAFFERJ@BKNLVMS.BITNET
Message-ID: <8809081429.AA16724@ucbvax.Berkeley.EDU>
Source record: 116579

The 'emacs' editor under Un*x has a feature to let you read digested mail
one message at a time, and even delete or keep individual messages from the
digest.
I don't know the details (I've just gotten started on Un*x, and our Ethernet
is busted so I'm not gonna go and look it up now), but it's in the manual
somewhere of course. When our Ethernet is fixed, I'm going to subscribe
to digested lists on that machine (this machine can gateway), so I can
use emacs to read my mail. It's much nicer than hacking out the stuff you
don't want with an ordinary editor prior to, say, throwing the file on the
printer (and infinitely superior to throwing the *whole* file on the printer).

1426. Atari 8-bit viruses

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-08 04:26:00 UTC
From: SHAFFERJ@BKNLVMS.BITNET
Message-ID: <8809081639.AA19101@ucbvax.Berkeley.EDU>
Source record: 116580

I'm re-sending this message because I never saw it on the digest.
Those of you who saw it before somehow (at least one person did), please
accept my apologies.

Despite the claim in this discussion group about two months ago (*very*
approximately) that an Atari 8-bit virus would be difficult to write, I
recently read in an article in Atari Explorer magazine that there is an
Atari 8-bit virus going around. Unfortunately, the article didn't go into
much detail -- in fact, hardly any detail at all. I don't remember the
specific information about the article (what issue, who wrote it, etc.),
but it was an article on viruses in general (not just on the Atari) and
was quite good in that respect, mentioning Scores, Brain, the Israel Virus,
CHRISTMA EXEC, and other recent viruses.

So, can anyone give me any information on the Atari 8-bit virus? I haven't
found the time to check CompuServe yet (or any other bulletin boards), but
if I find any information elsewhere I'll be sure to post it here.

1428. Re: Atari 8-bit viruses

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-08 23:04:17 UTC
From: gdtltr@vax1.acs.udel.EDU
Message-ID: <1873@udccvax1.acs.udel.EDU>
Source record: 116582

I read that article. There was no specific reference mentioned, so I assume that the writer meant that 8-bitters are not exempt from the possibility of a viral infection. In fact, I have had an idea about how one might manage an 8-bit virus, but even then it would be limited and fairly easily detected by an experienced user. It would be even easier to fix. The effect of triggering a virus are only limited to space and the imagination. I won't go into the details of my ideas so to avoid getting sued when a clever user implements my ideas and wipes out someone else's data.

1429. Re: Atari 8-bit viruses

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-09 04:16:38 UTC
From: rjung@nunki.usc.edu
Message-ID: <1336@nunki.usc.edu>
Source record: 116583

Well, I just looked at that paragraph you were (probably) referring to,
about "Nor are 8-bit Atari owners completely safe". From what I read though,
from the way the "virus" is supposed to attach itself to another program,
it seems more like the 8-bit "virus" isn't a virus in the traditional sense
(eg, a self-sustained replicating program), but more like a modification to
an existing program...Can we call this a retrofitted Trojan Horse instead?

I'm no hardware/systems expert, but I can't see how a boot-sector-type
virus could work on the Atari 8-bit. You MIGHT try to write a self-booting
disk "utility" that infects whatever disks you use with it, but that is hardly
a virus, is it?

Overall, it seems like 8-bit "viruses" is just an extension of the idea of
maleviolent code. Maybe John Jainschigg decided to take liberties with the
definition "virus" to inject some 8-bit interest into the article (Let's face
it, the virus problem is easier to inflict on the ST world -- Whew!)

(What am I saying? I've got an ST too! [But _2_ 8-bits! Hahahaneeharhar])

1430. 6502 timing question

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-09 16:44:00 UTC
From: BIW109@URIMVS.BITNET
Message-ID: <8809091641.AA15253@ucbvax.Berkeley.EDU>
Source record: 116584

I have a question on the timing of the 6502. Which requires more
time, an LDA, or an STA? The reason that I ask is that I am working
on an interfacing project, and am running into problems. I think that
the problem might be caused by too much delay time in the interface
its self. The problem is that I am able to read from an external port
(in this case, an A/D converter) with 100% accuracy, but I an unable to
write to another port (a D/A converter made from an 8-bit latch and an
R-2R resistor ladder). Writes to the D/A converter are sucessful only
about 10% of the time. The interface circuit introduces the same delay
before activating each port. I think that I am able to read ok because
on the fact that the cpu allows at least 250ns for the memory (or what
ever is on the bus) to respond. Can anyone tell me how much time the
cpu allows for memory (or what ever) to latch a byte from the bus?

The timing for reading and writing bytes to memory is roughly the
same. In either a store or a fetch, one memory cycle is used (during the
first part of the cycle, phase-1, an address is placed on the bus by the
processor. Devices connected to the bus decide during this time if they
are being addressed; if the chip enable is set, then depending on the state
of the R/W' line, the enabled device either stores what it finds on the
data bus during phase-2, or outputs information onto the bus). There are
a number of signals which must be dealt with properly; if you are having
difficulty on writes, you might check that data from the bus is getting
clocked into your latch during phase-2 proper (i. e. the information actually
has time to settle before you read it -- this would be a case of reading
into the latch too quickly, not too slowly. Note that a latch is sufficiently
speedier than memory that the speed of your interface should not be a problem).

My information is a little stale; also tinged with M6801 terms. I
hope this is of some use to you.

1432. Re: Atari 8-bit Virus

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-09 21:33:14 UTC
From: Thufir@cup.portal.COM
Message-ID: <8809101801.1.133@cup.portal.com>
Source record: 116586

It might very well be possible for an init segment in a multiple segment binary load file, that would be a virus that could reproduce its own segment into another binary file, to exist on the 8-bit. However, due to the relative slowness of disk i/o when using a standard drive, and the beeping/clicking associated with it, it could hardly go unnoticed. However, someone with a MIO or very fast hard drive, may not notice such an operation taking place, due to the speed and lack of beeping. It is quite possible, but due the relative simplicity of the 8-bit's operating systems (dos and such), it most likely wouldn't be able to go unnoticed. (I'd sure notice a file such as Textpro making writing sounds when loading, or a copy of Express 850 that was 500 sectors long, or a strange occurance in my STARTUP.BAT file, or even a file that never existed before suddenly popping up.)

Yes, it's possible, but we are less vulnerable to having things go unnoticed.

One other thought.

When I opened up my 800 a while ago, I found a Rockwell 6502B. For write data, Rockwell's specs for the B version provide a minimum hold time of 15 ns. from fall of phi2 (end of phase-2). These timings are at the processor chip pins.

If you are using a flow-through latch ('373 or similar), the data has to be valid when the latch closes and has to remain so for, e.g., at least 20 ns (TI's specs for 74LS373). In most designs, the write strobe is a gated phi2. So things are already problematical. They will probably work because the capacitance of the data bus is working for you and most TTL parts I've encountered are considerably better than their specs, but ...

I have seen designs (gated phi2) in which there are more logic delays on the write strobe than buffering delays in the data path. This could push things over the edge (data corrupted before latch closes) and account for the marginal operation you observe. If I recall correctly (I don't have the schematics at hand), the system phi2 on an 800 might already be leading the 6502's phi2 by the difference between two gate delays. The XLs and XEs actually use a customized 6502, which handles phi2 differently and might be better or worse. If you are right on the edge, going to a 74F latch might bail you out (hold time on a 74F373 is 3 ns, for example). Bypass generously. Also, hold times for edge-triggered flip-flops are typically lower than for latches, but you don't get the flow-through and you can't use the leading edge of phi2 (data not speced to be there yet).

Finally, I have seen MOS parts with internal latches that have very long hold times compared to TTL. If you're using such a part, simple interfacing might just be incompatible with reliable operation.

I hope that some of this helps and that none of it is too misleading -- it's been a long time since I've looked at my Atari. I suggest investing in some schematics and data books if you can find them, then checking the timing margins on all the relevant signals.

Source record: 116588

Based on my (limited) experience, you may find the problem has to do with something as simple as the polarity of the strobe put out by the computer being wrong for the latch you are using. You need to understand the timing of the data on the bus and the strobe signal your latch is responding to. When you get it all figured out, a few nanoseconds shouldn't be critical; but things like the polarity of the strobe or the edge you sample on ARE critical. In general, you should never rely too much on the time delay along a signal path relative to another path (e.g. the strobe). Instead, you should derive signals in such a way that they HAVE to have the right timing sequence. (Sangster's First Law of Logic Design: If you want signal B to happen later than Event A, DERIVE signal B from Event A.)

Are you reading data directly off the parallel bus, e.g. on an 800XL, or are you using the joystick ports as an output? In either case, give me a little more detail on your interface and I might be able to help.

-John Sangster / jhs@mitre-bedford.arpa

1435. Re: Atari 8-bit viruses

Newsgroup: comp.sys.atari.8bit

Atari 8 bit viruses, etc. I am a pretty good programmer, and I can assure you that an 8 bit boot virus would be very easy to write for the Atari DOSes. Writing one for the SpartaDOS series would be more difficult but still not hard for a competent programmer.
I haven't seen any, and hopefully I never will. I have thought about them and have come to the conclusion that a multivirus (one that infects Boots, Com programs, and Basic programs) is quite possible. It would require an excellent programmer and some time but would be relatively easy to write. Luckily, those quality programmers are usually in the process of writing other (more useful) programs.
In talking with others (when the virus question first came up) I found that the ways to activate a virus were moe numerous than the people I talked to. Each one of them had 2-3 nasty thoughts on how to cause a virus to activate and how to create strange viruses.
I shall end by saying that should any of these ideas be applied to other computers, they could effectively prevent the tracing of a virus to its source which (as far as I am concerned) is of greater importance than eliminating the virus in the first place.

1436. Re: 6502 timing question

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-10 22:00:18 UTC
From: Ordania-DM@cup.portal.com
Message-ID: <8950@cup.portal.com>
Source record: 116590

```
Here are the timing specs for LDA and STA:
opcode mode cycles
LDA imm 2
" abs 4
" z-page 3
" (ind,x) 6
" (ind),y 5*
" zpage,x 4
" abs,x 4*
" abs,y 4*
STA abs 4
" z-page 3
" (ind,x) 6
" (ind),y 5*
" zpage,x 4
" abs,x 4*
" abs,y 4*

* Add 1 cycle if page boundary is crossed.

As you can see, they take the same amount of time regardless of the opcode,
the timing is dependent on the addressing mode, and where the data to be
addressed is located (within a page as opposed to across several pages).

I don't know if this will help you much, but it is what you asked for.
```

1437. Re: 6502 timing question

Newsgroup: comp.sys.atari.8bit

The question was asked:
"What is the difference between the time a LDA instruction takes, and the
time a STA takes?"

It depends on the indexing, zero page stuff, etc., but in general, a store takes
one clock cycke longer than the load, add, or, and, etc.

Charles Marslett

Any comments on the Gorilla RS-232 printer for use with an ATARI 800. I have a chance to pick one up for $60. It is unused and comes with the R-verter RS-232 to ATARI serial bus converter. The seller had a 400 and claims it only works with an 800 or 800XL. Is this true? Is this a good deal?

Thanks,
--

I would be somewhat wary of this claim about the 400/800/800XL business.
The serial ports for the 400 and 800 are the same (the old 800; it's possible
the XL is different -- though there's no reason why it should be). One
possibility is that there is something wrong with the serial port on his
400. I once encountered an 800 which didn't work with a disk drive, although
it did work with its printer interface; as I recall, one of the lines on the
serial port didn't work, but the interface didn't use it. Or perhaps it was
that the interface wouldn't pass one of the lines from one serial connector
to the other. It's been a while. But anyway, I would be extremely
hesitant to buy the thing without seeing it work on MY machine. (Note that
my Atari cynicism is born of numerous accounts of things like I just
mentioned, having to do with just about every aspect of the old 400s and 800s.
Particularly having to do with things which would run on one machine, but not
on a seemingly identical machine). If you do try it out, and it works,
then it is probably worth the price. About the only thing that ever goes
wrong with these setups once you get them working is an occasional chip
burnout.

1440. ZMAG

Newsgroup: comp.sys.atari.8bit

Message-ID: <1886@udccvax1.acs.udel.EDU>
Source record: 116594

I don't know about anyone else, but I find the Atari Zmag a great source of information on Atari 8-bit topics. In fact, I let my Antic subscription drop because Zmag has most of what I want (of course the fact that Antic is shrinking away into nothingness has nothing to do with it). Since I have never seen a Zmag posted here and think you might enjoy it, the latest copy (as far as I know) follows. Let me know what you think of it and if I should continue posting them here.

DIAMOND UPDATE

DIAMOND looking better all the time, will be shown at the Glendale Show, and so will the "ST JR" (the GOS remake, formerly presented by Merrill Ward, but no longer). Also, Merrill Ward will be marketing DIAMOND...and WON'T be Merrill Ward anymore. They are relocating from Palm Springs CA to Washington DC, and will be called USA MEDIA.

Alan Reeve, DIAMOND programmer (in college in Illinois!) is even hopeful about ATARI packing DIAMOND in it's final CART form in with new XE's and XEGS systems....

Diamond is planned to include a PAINT, WORD PROCESSOR which is said to be more like the TIMEWORKS package for the ST (top rated desk-top publisher!

Interestingly, Alan says that he had abandoned the DIAMOND project last winter, but after John Nagy wrote about it again in April (in CSHOPPER and in ZMAG) he got such a good and immediate reaction, he went back to work on it, with bigger hopes and grander goals.

MID-MICHIGAN UPDATE

We use this space to publically ask the staff of MAM to fill us in on what the current 6 month plans. As editorialized here a few weeks ago, we stated that there appeared to be less and less user group news and articles. With the support of 8-9 local users groups, it seems to us at ZMAG that more interest should be given to local reporting then the current style used. How about it?

NEW ADDITION

We are happy to announce the addition of Carlos Hernandez to the staff of ZMagazine. Carlos will take on the function of Assistant Editor.

We are also happy to announce the promotion of Ralph Mariano to General Manager of APEInc. Ralph we now manage all three present publications.

LABOR DAY TELETHON

Although not Atari related, we encourage our readers to donate what-ever you can to the Muscular Destrophy Association. Call 1-800-FIGHT MD

OASIS BBS UPDATE
by Glenda Stocks

No one else will tell you all about OASIS, so I will. $25.00 will get you 3 DS/SD diskettes with 6 sides of info, including two drive sample BBS with 23 modules working in it. All new docs written by me, each mod is also given separately with its own docs. There are 22 main menu options that each sysop decides what to offer from them. Totally flexible, customizable.

Every main menu option's letter can be picked by sysop. The following features can be executed from any of the 22 main menu options:

o User lister o Caller log
o Sysop created menu o Add a BBS number module
o User poll o Trivia game
o User stat lister o Survey game
o RLE movies o BBS daily stat lister
o Download base o User ul/dl ratio lister
o Eliza game

All of the above could be on one single sysop created menu. The download base program allows sysop to name and create his own subdirectories (or use no subdirs at all) and offers user ability to search files by the following criteria from a simple small menu:

o Filename o Language
o Type o User level
o Date o Files per page displayed
o Categories to include or not in search (search all)
o New files since last logon

DL base automatically displays 40 or 80 columns from one module. Eight msg bases that can be created first and allow msgs to be any size and compact at logoff.

For ML programmers OASIS IV has added many new equates and built in BBS routines just for programmers to write modules for OASIS. The following modules need to, or can be written, of course I cannot write them all, as I am working on other programming projects, including OASIS V.

o Automatic board backup at set times
o Automatic msg base exchange (networking)
o Upload module to get correct file extensions from users
o Any game module
o Password application procedure
o Logon sequence
o Logoff sequence
o Download base with file descriptions
o Ymodem batch file transfer
o Modem call answering sequence
o Waitscreen stat lister for sysop waitcall screen
o Various sysop online utils including other DOS functions

These are just some ideas of what can be done, based on the equates provided and sample modules already in use. Added to that will be OASIS.PAL which will allow offline debugging of modules. Also, I will be revising the current 30 modules (8 of which are required to run OASIS IV and they total 10,054 bytes = 78 single density sectors of your system disk, which means all other modules are optional, and the BBS can otherwise run completely without any other modules needed to be online... important for small system operators), the source code to each revised module will be posted.

There are three OASIS support boards, which will be beefed up as I revise modules, to provide plenty of access to support.

XBN-I 617-767-0760
PC PURSUITABLE MABOS node.

XBN-II 508-580-8722

XBN-III 508-559-6844.
Other Oasis Features:

o Eight msg bases that can be created first and allow msgs to be any size and compact at logoff.
o Eight random mini messages at main menu prompt, great for BBS ads.
o Various methods of user security levels including many within modules that can be controlled by sysop.

You can have a totally open BBS and still support special group in a secure way.

More Features:

o Online sysop term program including 1k XMODEM/CRC protocol, and text capture.
o User support for VT52 (for ST) and ANSI (for IBM/PC) graphics
o Mini menu
o No-apply PW module
o Users can write your trivia, surveys and polls and run them on your BBS
o Msg bases can already be exchanged among oasis boards
o Fmail can already be sent on oasis boards
o Arcview of files online will show ALFcrunch also
o Online GLU.COM sysop module
o Jump to DOS and use all internal SpartaDos functions online
o Validate users online
o UL/DL ratio, and ability to allow free DLS from a certain drive, great for Zmags or user groups to get files not counted against their ratio.
o 300 baud lockout and user level lockout options
o Modules can be only up to 5632 bytes = 44 single density sectors
o Not a limitation but rather a restriction that demands tight program code as opposed to loose and sloppy code, and also insures the continuance of the OASIS theme of big system power on small system storage.
o DLBase is a prime example of the power than can be packed into a small module.
o 98% of all OASIS menus and modules and the message base reading functions are all HOT KEYED
o Users do not have to WAIT for menus to finish displaying or messages to finish printing. Users just hit the key they want and the BBS interupts what it was doing and executes the option selected.
o Modules written by me include sysop alterable functions, not just text prompts. There are actual program functions that can be determined by the sysop without his having to be a programmer in such languages as basic, ML, or action.
o Sysop can control HOW a module works and customize how it interacts with his system's drive partitions.

OASIS modules are not use as is, but rather sysop modifiable. You also are not restricted as to where modules are kept on your system, nor where their support files are kept. CONTROL-C can be used almost everywhere on menus and modules to abort functions, also CONTROL-S and any key to resume is available throughout the BBS. Also, the more prompt can be continued with any keypress, not limited to just return. Yes and no questions can

be answered NO with any key other than [Y]. Downloads can be sent and arcviewed in the message bases.

Modem and BBS configuration is setup according to two codes that your modem sends to the software. Multiple options are provided to assist you in configuring your modem to send one of these two codes. Instructions help you to run a test mode to find which standard setup your modem fits.

Some of the standard equipment that have options are:

o AVATEX NON/HC, 850 o P:R
o MIO o ATR

Any modem/interface combination can produce one of the two codes. Once you find your config, your BBS runs perfect, meaning that it resets immediately on all dropped carriers everywhere on the system including such trouble spots as: during logon, during uploads and downloads, while reading messages, while within a running module, at the main menu, everywhere you are assured of system security by fast reset, within 2 seconds or less, so no one can logon as someone else after a dropped carrier. Also you can issue any modem commands to your modem at the waitscreen and at logoff, great for the multi-featured smart modems.

Almost any modem and interface combo can be configured to run OASIS, even the SX212 can run it DIRECT CONNECT! with no interface required!

The theme of OASIS IV and will be for OASIS V, is small system storage CAN run big system features. Small tightly coded external and optional modules, allow larger systems to add more. Easy to setup and well written docs that leave all to your imagination and the sample BBS allow current sysops to go online immediately, customize as they learn the BBS, and then redo their own BBS from scratch, totally customized to look and do what they want.

Low and reasonable price of $25.00 and ample support from three support boards all run from the same household insure timely postings of new modules on all 3 boards at the same time, and the ability to get help if a line is busy.

PC Pursuit access is available from one board. OASIS strives not to be like any other BBS, does not consider itself 'behind' any other BBS, but rather OASIS is a powerhouse BBS, packed with behind the scenes practical sysop power for small system owners.

OASIS can run on an XE-Game system, SX212 modem direct connect, and XF551 DD/DS drive. OASIS is filled with user convenient amenities, like HOTKEY, control-C abort, and pause/resume capabilities throughout. Also simple and straight forward use of msg bases and download bases, that means that user use your BBS to its fullest without the need for help files, or much fumbling around and getting discouraged.

Note: Just thought it was worth mentioning that OASIS helped in preparing this text for re-print in ZMag, it [OASIS IV] gives the user the power to

format his screen.

(SYSOP dick) <Swinging Gavel> BANG! Ok, protocol for todays meeting: if you have a question or comment type ? or !. I'll keep a running list of names and call on each in turn. When you're finished with your question or comment type GA (for Go Ahead). I'm not going to formally introduce everybody -- it'd take 15 minutes. We're here today to talk about the future of Atari Publishing and we have the CREAM of the industry today! Does anybody have a short opening statement they'd like to make?

(John @ Explorer) I think there *is* a future for Atari Publishing because, apparently as we've all seen in the past few months of stock issues, rising prices and new product announcements, there is apparently a future for Atari itself.

(SYSOP dick) It's been a long time since we've heard death of Atari rumors!

(NORM) ANTIC, ANALOG, EXPLORER, COMPUTE---I USE ATARIS IN THE CLASSROOM YET I see very little serious educational programs, utilities, articles in your magazines. I keep searching and hoping!! Any...???

(John @ Explorer) ANALOG, Antic, ourselves, and I believe the other magazines have made a concerted effort in the past six months to increase coverage of educational issues ... quite frankly, however I think my colleagues will agree with me that educational software particularly software based in a coherent curriculum -- that is consistent educational software of some real value is exceedingly difficult to track down. There is a real subculture and not a highly structured one, that teachers are using as a resourc for Atari-related educational tools...but the situation isn't pretty What, if I may ask, are your personal goals as an educator in using Atari computers?

(NORM) Merci,John! Word processing in composition writing, electronic workbook, modem communication in for lang. fun programs to add zip to the classroom teaching/learning.

(Clay @ ANALOG) I think that what John was trying to say is that we all look to our mailbox for the content of the magazine. Few people have the skills in both teaching and programming/writing to come up with publishable educational software or articles. We get lots of pseudo-educational programs -- the same old math drills and such that were cliches 5 years ago. I would say to Norm that, if he has something in mind and can present it in a publishable form, ANALOG will be happy to send him a contract.

(Tom R. Halfhill) I think Clay has made the point I wanted to make. The material that magazines publish is largely determined by the material which is submitted. If Atari users wish to see more coverage in a certain area, or more coverage in general, they should submit more material to the magazines.

(SYSOP Dick) As an 8-bit user, I've grown concerned about the fact that many of my favorite 8-bit magazines have been having 16-bit babies. Does the birth of these new magazines signal a diminishing level of support.

(Clay @ ANALOG) Dick, Dick, Dick... I can't believe people are still asking that question. ANALOG computing (the mag) is our bread and butter! There's no way in the world that we're going to let it slide in favor of ST-Log. We _are_ very excited by the possibilities offered us with a new computer and a new magazine. How could we not be? But as long as there's 8-bit computers out there, there'll be ANALOG Computing and I think you can see that the quality of the magazine hasn't slipped (we're a little late, but we're catching up!)

(Tom/Rhett (COMPUTE!) Magazine support depends on reader interest. When a magazine notices that readership is declining, and submissions are declining, then it must decide if the current level of support should be maintained. At COMPUTE!, we receive user group newsletters from Atari clubs all over the country, and have noticed that a major issue in Atari user groups today is the fear of declining support for the 8-bit Ataris. Newsletter editors complain of a lack of 8-bit articles submitted, and of a lack of attendance. If a magazine perceives the same drop in interest, naturally it will evaluate its coverage. Atari 8-bit users should maintain their interest in reading the magazines and submitting programs to help guarantee continued support.

(John @ Explorer) I don't perceive a falling off of interest in 8-bit material as my colleagues have suggested; but what I *have* noticed is a very drastic and upsetting falling-off of advertising support for 8-bit product. Being real for a second, it's advertising -- i.e. the marketplace that determines the market, and ultimately weighs on the content of a magazine. Those of us who, like Explorer, have not brought out separate 16-bit subunits or books, but who support both machines in our pages, are striving to maintain a balance reflecting readership while that balance is continually thrown off by revenue analysis.

(Erik @ Kyan) Well...seems everybody is calling the ST mags 'subunits' and 'babies' but to me, they seem a lot better than the mags they broke free from and feature a lot more professional material, not assuming the reader is a total beginner.... (START for instance).

(Erik @ Kyan) oopps not that START...

(BARTENDER) THE FUTURE OF 8 BIT SEEMS DIM TO ME AS AN 8 BIT USER...

(Erik @ Kyan) assumes reader as a beginner but that start has more power-user/programmer geared articles, sorry guyys GA

(BARTENDER) AS EVEN MY REGULAR ISSUE OF ANTIC SEEMS TO OVERRUN WITH ST STUFF. I HAVE TO READ MY MAG CLOSELY TO BE SURE I DONT TRY TO LOAD AN ST FILE FROM THE DISK I JUST BOUGHT FOR MY 8 BIT I RETAIL ATARI PRODUCTS AND ANTIC IS NO LONGER ONE OF THOSE AS SALES FELL SHARPLY AFTER THE ...

(Charlie @ ANTIC) I agree that the backbone of the editorial sections of a magazine are governed by it's mailbox, but it's also governed by it's wallet. When I joined ANTIC 3-4 years ago, we had 7 members producing Antic (writers editors and programmers) today, there are three people doing the same job (and at that, we're also helping with Antic's OTHER mags.) Two days ago, we had an in-office discussion about the ST vs. 8-bit. The problem was trying to identify the FUTURE 8-bit market. "Who," we pondered, "was going to buy an 8-bit machine when the 16-bits could do so much more, yet don't cost that much more." Apparently, hardware & s/w manufactureers feel likewise, did ANYONE see 8-bit products at WCCF or Hannover?

(CRAIG) I HAVE A 8-BIT AND I LIKE TO ADD THAT THE POEPLE ARE THE ONES YOU MAKE YOUR MONEY OFF SO WITH THE PRICE OF 120 FOR THE XE/XL YOU CAN SEE ...WHAT COMPUTER POEPLE WILL BUY THANK YOU.

(Clay @ ANALOG) I don't see that the 8-bit audience, in general, is falling... But the point was previously made, and I agree, that 8-bit software support and thus advertising $$$ ARE falling off. I think all the publishers here will agree that there's two main reasons why we include a small amount of ST related material in our "8-bit" magazines. The first is because we truly believe that most 8-bit users are interested in the 16-bit computers and would like to be kept informed. Secondly -- and this gets back to the fall of 8-bit software support -- putting St articles in the magazine attracts more advertising $$$$ and a magazine MUST have that income. I think the major challenge the 8-bit magazines face now, as far as content goes, is finding original, unused ideas. How many times can you publish an article on how to redefine character sets?

(Mark @ Supra) Ok, responding to the problem of advertising dollars falling off, the market is fast shrinking. The amount of time to develope a good product, write docs, get addvertising going is a long time, anywhere from 3 months (if you are luckey) to a year. So we as a manufacturer in deciding on new products to do must look a year ahead at the market. At this time we are taking the point of view that we can not afford to produce a new product strickly for the 8 bit market, but rather if we can move a product over to the 8 bit line, then it will be moved over. Case in point

is our sub 200 2400 baud modem, it would have never been developed for the 8 bit line, but since it is an easy matter to move it over it will be produced. Also in talking to software offers, piracy is a main concern, plus the shrinking market.

(Jack @ JOURNAL) Devil's Advocate position for a sec...I believe that the 8-bit... user begins to perceive his market as "disappearing" due, in part, to the "splitting off" of the mags, and this tends to be made more obvious to the advertiser, into a narrowing circle. Do the 8-bit users out there really still _care_, or do they feel that it's only a "matter of time" before they either move "up" or "out"? I know that at the local users group level, we have discussed the division of the group, several times, and each time, the 8-bit people want to REMAIN as a part of the _larger_ group. Perhaps some of the publications have created their own petard, in making what was originally believed (and may, eventually prove to be) a WISE decision.

(ROBIN) HELLO. THIS IS A QUESTION FOR ALL THE MAGS.. I'M A NEW MEMBER TO ATARI*SIG AND HAVE BEEN READING UP ON ALL THE MESSAGES ..... I'M WONDERING WHY WE NEVER SEE ANYTHING ABOUT THIS SIG SYSOPS IN THE MAGS??? ...

(Tom/Rhett (COMPUTE!) ANTIC made a good point about the future of the 8-bits. We have thought the same thing. If eight-bit coverage seems to be dropping off, I think there are a few reasons First, the ST mags can provide better coverage because they have the advantage of a bound-in (or optional) disk. This allows larger programs, and programs which are written in good compiled languages Also, we noticed a decrease in quantity and quality of Atari articles soon after the ST came out. Both the articles submitted to us and to other magazines (sorry, guys, just being honest) I think this is due to a migration of the best 8-bit programmers to the ST and Amiga...

(Tom/Rhett (COMPUTE!) The best programmers will always gravitate to the hotest, latest machines. The 8-bit market also lost some very good programmers to the C-64, Mac, and other computers that sold better or were more attractive to programmers for various reasons.

(Bill C.) Well, since Atari is supposedly making so much money on the sales of 130XE's and other 8 bit hardware, (including sales to me, guys). I wish, no, DEMAND, that they get into the ring on this software availablilty problem. If they would push what they sell with the publishers, we wouldn't be in such bad straits. As a loyal Atari user, I expect this kind of support on their part, especially if they want to continue to get my bucks!!!!!!!!

(John @ Explorer) Well, first off, to answer Bill, Atari *is* in the ring on this software availability thing. Virtually the only truly substantial 8-bit product I've seen has been coming, hook or crook, off the assembly lines at Atari -- this is excepting the slow but steady trickle of quality software from a number of super-loyal software houses that have stuck by the machines. But the real point I'd like to make is I think we -- all of us -- are perhaps suffering from a failure of the imagination here. As

Bill says, Atari *is* selling a whole lot of 8-bit machines, and is continuing formal support for the hardware the operating system, peripherals and software -- all of the magazines here probably represent a combined subscriber base of something on the order of 300,000 to half a million, with lots of overlap -- but there are millions and millions of 8-bit machines out there. As a whole the 8-bit side of the industry, and that includes Atari, seems to be able to sell to these people, but not to reach them on a consistent basis it's extremely puzzling to us.

(Bill C.) I don't want Atari to publish. I want them to push other publishers to port...

(JOHN NAGY) Our club, CHAOS, has seen the same migration of users to ST, most 8-bit users..

(Bill C.) Stuff over to the 8 bit ataris... Sorry.

(JOHN NAGY) have seemed to accept the idea that they are all ST owners that havent gotten one yet. this isnt really necessary but the atari company and all of us following behind have sort of allowed the 8-bit to lose any focus as a viable machine there is a real reason to use an 8, and not to get an ST other than just becuse it is cheap, there are many things (games not being the least of them) that the 8 can do fine. WE NEED TO PUSH THE 8 as a real machine at the retail, or else we see it fall out of notice. Too many beleive that the 8 is even out of production!.

(BARTENDER) THE GENERAL TONE SEMMS TO REFLECT A CHANGE IN ATTITUDE BY ATARI SUPPORTERS TOWARDS THE ST LINE. YET THE ATARI 8 BIT COMPUTER IS BY FAR THE BEST DOLLAR INVESTMENT IN THE COMPUTER MARKET. MOST REPLACEMENT PARTS ARE AVAILABLE FOR LESS THAN $5.00 EA BAR A FEW SPECIAL.. ITEMS AND THE WEALTH OF ALREADY EXISTING SOFTWARE AND MANY YEARS OF PAST ISSUES OF MANY PUBLICATIONS MAKE THIS COMPUTER TRUELY A LANDMARK IN 8 BIT HISTORY. HOW ARE WE AS EXPERIENCED PROGRAMMERS TO EXPECT A 13 YEAR OLD NEW USER TO EVEN BEGIN PROGRAMING WHEN WE USE A ZERO PAGE LARGER THAN THE COMPUTER WE LEARNED ON?

(SYSOP dick) I've noticed the steady growth of on-line publishing by the magazines and newsletters. Antic at CIS, Analog at Delphi, ZMAG everywhere! Even Omni and Playboy. Does this signal a decline in the value of the printed word? A new way to serve readers? what does the shift to online publishing mean I'd appreciate any thoughts from the mags and newsletters on the shift to online publishing.

(Charlie @ ANTIC) (Ooops! Theme change...)...

(SYSOP dick) Not necessarily, Charlie. I want your thoughts on ANYTHING!

(Charlie @ ANTIC) Agreed, there's been a change in attitude but in a different way. In a recent ANTIC ONLINE survey, we found that the largest chunk of users want BUSINESS software and prefer Product Reviews and New Product announcements to type-in programs. (At the CompuServe booth at WCCF virtually EVERYONE I spoke with wanted to learn about computer business applications...only a handful asked about programming SIGS (forums). There are only a handful of RELIABLE business application programs for the 8-bit. So as ST prices continue to plummet and software

lists and catalogs grow thicker and heavier, WHO is going to buy tomorrow's 8-bit machines? ... Personally I love my 800 (if not for it, I'd not get a paycheck) but it looks like the tides are shifting.

(Joe T.) First... for all the publishers: Why is it that the programs for most other machines have well written graphics, text, etc. but when they are changed to Atari, they only look slightly better than the original Pong game? It looks as if they are thinking "we'll just make a quick version for the Atari machines just to keep those few subscriptions" ...

(Ripp) Piracy is a major contributor to that!

(Joe T.) I understand about piracy, but a lot of the type in programs that include (a picture on how it will look on different machines shows that not much effort was put into the Atari versions.

(THOMAS E. REED) Having suffered through a girlfriend with a Radio Shack Color Comp... both of which, thank the Lord, are now gone. I was suprised by the tremendous advertising support for the CoCo magazines from local dealers. Why not that same kind of support for Atari mags? Also... Since so many users are upgrading their machines with extra memory, how about some discussion of Atari upgrades in the magazines? Lots of people love their 8-bits. Mine does everything I need in a computer, and I don't see a reason to change.

(SYSOP dick) Clay==> (Maybe you can give us an idea why Analog went online and Tom/Rhett can give us an idea why COMPUTE hasn't gone online)

(Clay @ ANALOG) Well, I wasn't at ANALOG when the original TCS went on-line but the reason, I'm sure was that it gave people an alternative to a disk subscription. It's a lot nice to be able to download those specific programs you're interested in, than to put up the cash for a disk sub. We moved to Delphi because supporting the TCS became an overwhelming task (over 2000 subscribers on the TCS), plus we needed the extra disk space Delphi could provide. Once we had the programs on-line, it was only logical to port the text files over from the typesetter and put them on-ine, too. Now a change of subject.... I wanted to say before that 8-bit users have one sure way to protect their future -- and that is to BUY! Buy software, buy hardware, buy magazines. As long as there's money to be made, the computer will be supported. We have to feed our kids, too Though we love our work, we have to bring home a paycheck.

(John @ Explorer) Answering a few questions: as to the issue of how magazines tend to support 8-bit systems with type-in stuff ported from other machines, the gentleman who spoke was absolutely right in his estimation of the mental process in most cases...however there are notable exceptions -- Family Computing, for example, where I used to be Sr. Tech. Editor, had an in-house programming staff that were all rabid Atari programmers, so even though there was little interest in editorial coverage of the machines, per se, we always made sure that Atari 8-bits were covered with the best stuff we could put together...On the subject of "online editions," we're looking at a wholly new definition of the

concept of magazines. What started as an "efficiency measure" -- something to render better service to current subscribers and readers, mostly, has turned into something quite different. Online editions are a new, more fluid medium than print can ever be.

(JOHN NAGY) Printed mags are NOT dead, but they COST a lot to make. Onlines, like ZMAG can get out fast with the costs of production being taken over by the readers this lets one try ones hand at publishing without the huge risks of advertising needed to pay for the big investment in printing and distribution. I do feel that magazines can't be replaced, as there can be no better way to be able to skip through an article or see what might be there for you ... onlines make you wait through all the stuff you DONT want to get to the part you DO. But the mix we have been gettting recently has improved both means of publishing.

(Ron [ZMAG]) John is correct in everything he stated. We produce an issue each week with the intention of providing information about printed mags, CIS, and the information services for our readers. We have 100+ bbs systems carrying each issue. Many of which use the information for thier local user group newsletters. John Nagy has been one the few who has provided information with the purpose of user group usage. We can get news out faster, but cannot provide the space printed forms do.

(jpp) At first there were general purpose computer mags then there were special purpose mags then came the IBM and general purpose and IBM became the same new users won't find out about ATARI and I suppose most of your readers already have ataris. why not start real general coverage mag leave the program listings for your online unless they are generally applicable also the 8 bits are cheap and should be good hacks would like to see hardware hacking articles.

(Mark @ Supra) Responding to online magazines and bbs... The whole idea of what a bbs is and how it works needs some new thinking. The biggest thing I see is that the term programs and the bbs service need to compliment each other, rather ie.. menus, I hate having to have the same info sent time and time again. I know that several services are working on this, but before bbsing can become useful for the general populas some user interfacing needs to be redone.

(Tom/Rhett (COMPUTE!) We'd like to answer two earlier questions that seemed to be aimed at COMPUTE!:

1 -- The quality of programs translated to the Atari;
2 -- COMPUTE! online.

First, it is easier to write a good, original program that takes advantage of the Atari's features if you start on the Atari. It's harder to translate a good program on another computer to the Atari. Also, it's a deadline problem, writing programs for many different machines. We also find it difficult to find enough good programmers for our needs. (In fact, we have had an opening for an Editorial Programmer for several months now, if anyone wants to apply.)

As for the online question -- we have considered this for a couple of years but there always seem to be projects of higher priority to carry out first for example, we wanted to start our various disk services and the ST magazine. There are only so many new projects we can handle per year. Especially since it is so hard to find new staff people that meet our qualifications. We've hired four new people just in the past few weeks and still have seven openings we can't fill. This limits our ability to start new projects that require a lot of planning, thought, and manpower.

(Charlie @ ANTIC) Compared to it's pen-and-ink counterpart, online publishing is in it's infancy (ANTIC ONLINE went live just a few yrs. ago in '84). The snags and glitches which tend to make online mags. appear "user hostile" at times, are being corrected. In AOL, we've added "Direct Access" pages for people who (don't like menus, highlighted new features, and working to make the whole schmeer easier to use QUESTION: What are the most important things an online mag. should provide?

(Charles @ ANALOG) As an answer to jpp's question about putting all listing on-line and removing them from the magazines, I feel that this is entirely unfeasable to do for two reasons. The listings one finds while scanning through the pages of any computer magazine -- while not always being of interest to everyone-- are there for a reason other than typing in. They are there to also read and learn from. You might not want the whole program but there just might be a few lines of code that you can and will use. Another reason has to do with the first time user without a lot of money. That kid next door who buys a few magazines each and every month from his paper route money usually can't afford a disk subscription or the on-line connect charges for download time that the services charge. He is perfectly willing to type in these programs and many do so (as I can tell by the phone calls we get each month about typing errors.)

(BARTENDER) I HAVE ONE QUESTION LEFT FOR ALL THE MAGS WHERE IS THE STUFF YOU GUYS READ TO ALLOW PEOPLE LIKE STEVEN KITCHEN TO LEARN TO WRITE SOFTWARE AS REFINED AS HIS ARE?

(SYSOP dick) Time for another "sense of the CO"...we've been on for some time now and ...

(John @ Explorer) Tristram Shandy, by Lawrence Sterne.

(SYSOP dick) the I've learned much. Do we wish to continue with the formal CO or just adjourn for informal....

(BARTENDER) A MONTHLY ARTICLE ON PROGRAMMING TECHNIQUE

(SYSOP dick) I want to thank everybody who participated today..... especially the mags and newsletters without your support most of us (especially me) would still be playing games..exclusively. I suspect there's a lot more love than money in Atari publishing...and we aof respect and gratitude for your support. I'd also like to thank Mike and Bill for their hard work in getting you all together. I'm going out right now and pick up extra issues and disks of all my favorite Atari publications. Thanks fellows, you've been super!

(SYSOP dick) <Swinging gavel> Adjourned!

PRESS RELEASES

A Day At The Races

This notice is to introduce you to a new software release for the Atari ST line of microcomputers.

After three years of research and development we are proud to announce "A Day at the Races". It was designed and written by Marshall Lake and Piet Francke and is being distributed by TEAM Software.

"A Day at the Races" is a simulation of the horse race track environment. Much more than the horse race itself, this simulation allows you to buy and sell horses, choose jockeys, and of course wager on races. Each horse and jockey have their own distinct attributes and abilities which affect the outcome of each race. Just like at a real track it is up to you to discern which abilities each horse and jockey possess and to attempt to pick the probable winner of the race. It is as close to the real world of horse racing as you can get without going to the track. The actual horse race itself is presented in exciting, nail-biting real time.

Dynamic data base files are kept for the horses and the jockeys. For the handicapper, all the various statistical items (including horses' past performances) are maintained to assist in an intelligent wager, horse purchase, or jockey selection. "A Day at the Races" is a multi or single player game.

This program will be available by October 15, 1988.

WPCORP OFFERS SPECIAL TO ATARI USER GROUPS

As part of a special product promotion, WordPerfect Corporation is currently offering WordPerfect for the Atari at a reduced price to members of Atari user groups until September 15.

The promotion will allow members of Atari user groups throughout the U.S. to purchase WordPerfect for the Atari for $155, a savings of $174 from the list price of $329. User group members must show proof of Atari users group membership to be eligible for the special offer.

Todd Ashman, director of WPCorp's Atari Products division, sees the promotion as a way to make WordPerfect available to dedicated Atari users at a more affordable price. "The product has been available for one year, " said Ashman, "but we wanted to give Atari users an added incentive to purchase the product this summer. We have a quality product and want as

many Atari users as possible to try it."

All Atari WordPerfect orders qualifying for the special price must be accompanied by a WPCorp users group purchase agreement, available from WPCorp. Interested users groups can call (800) 321-4566 or (801) 227-5900 to request the users group purchase agreement. The purchase agreement should then be submitted directly to WPCorp Atari Orders at 288 West Center Street, Orem, UT 84057.

WordPerfect for the Atari, which runs on the 520, 1040, and Mega ST, normally lists for $329. For more information about WordPerfect for the Atari or the users group promotion, call (801) 225-5000.
Contact: Rebecca Mortensen - Todd Ashman.

ST Transformer Update
by Darek Mihocka

Latest ST Xformer News, File Transfer Service, and

Using the ST with Atari 810 and 1050 disk drives!!

Users of the ST Xformer II emulator are familiar with methods of transfering 8 bit software to the ST. Using modems, null modem cables, and 5 1/4" ST drives (with the Xformer File Xfer Program), it is possible to transfer over files and most boot disks for use with the emulator.

I am pleased to announce the development of an interface for the ST, that allows 8 bit peripherals like the 810, 1050 and XF551 disk drives to connect directly to the 520/1040/Mega ST. Other devices, like the 850 interface, modems, and printers can also be connected. Everything just plugs in, so no warranties have to be voided.

Using a new version of ST Xformer II not yet released, it is possible to boot directly from these drives, thus allowing copy-protected commercial software to run under the emulator, and eliminating the hassles of the other methods. Now run Text Wizard, B/Graph, Visicalc, APX and Antic disks and many more. This opens new doors to the world of 8 bit emulation. Also, the new Xformer II runs on 512K, something the regular Xformer II can't do.

But that's not all! Users of the ST who are not particularly interested in emulation because they still parts of an 8 bit system will also find this useful. This interface allows for file transfers between the 8 bit drives and the 3 1/2" drives, thus allowing easy movement of files back and forth without the need of null modem cables or the 850 interface.

So if you have a 520ST with a single disk drive, and were considering buying another drive, consider getting the less expensive 1050 or XF551 drives instead of an ST drive.

Users who do not own an 8 bit disk drive, but who can still borrow one for a few days and get their hands on their user group's 8 bit library of disks, will be able to copy them to the ST in as little time as it takes

to copy the disks normally.

Although I do not plan to develop this feature unless there is specific demand, it is possible to reverse roles and allow the Atari 400/800 computers to access the ST as a virtual disk drive, thus allowing, for example, a BBS running on an Atari 800 to access a 520ST as a large RAMdisk.

I will produce the interface, and sell it for about $20 to $30. One of the reasons that kept me from developing this earlier is that I originally wanted the emulator to remain software-only. It will remain this way for users without access to 8 bit peripherals, but for those users who have access to both systems, this is a low cost add-on to increase their enjoyment of their ST.

At this time, I am unable to predict how long it will take make this available to all ST users. Hopefully only a few months. Right now the biggest stumbling block is finding those 13 pin 8 bit serial I/O connectors, which seem to be very scarce. Dealers and distributors interested in carrying this product should contact me by voice.

Anyone interested in buying one, please phone or write, so that I will know how many interfaces to initially produce.

File transfer service

Any Xformer users who are finding it difficult to port software over, either due to a lack of a modem or null modem cable, should phone me about arranging to send me their disks to copy over to the 3 1/2" format. With my prototype interface, I can copy hundreds of disks a day, and all I require is that you pay for the postage and disks.

I would be especially interested in obtaining a large database of public domain 8 bit software (a user group library?).

Other Xformer news

Other improvements are being made to the Xformer. I am working out the details of the full speed emulator, which is now on the horizon. However, I feel that I will prevent me from devoting further time to the Apple and C64 emulators, which have been pretty neglected so far, so I will be making the entire source code to ST Xformer II available. It is written in Laser C, so only Laser C users will be able modify it unless they convert it to another language first. Any developers interested in further improving the Apple and Commodore emulators will then be able to do so.

Sometime later in September, I will be putting up the Xformer support BBS, to allow modem users without access to Compuserve, Delphi, or Genie to call and download the latest emulator and 8 bit files. The number will be the same as the current voice number, and operate from around midnight to 6am EST/EDT.

Finally, if you are a user of ST Xformer II and have not yet registered your copy, please do so by sending your name, mailing address, phone, and a $20 money order. You will receive a manual and an updated version of the software and 8 bit files. Please indicate whether you want the regular double sided version of Xformer II, or the 512K single sided version of Xformer Junior.

The address is:
Darek Mihocka
310-D Bluevale St. N.
Waterloo, Ontario N2J 4G3
CANADA

In the US, remember that postage for Canada is about 5 cents more. The Xformer hotline, voice, and soon by modem, is (519)-747-0386.

Other sources of ST Xformer 2.10:

Compuserve - go to the ATARIDEV SIG and enter DL 5 (the Xformer download library)

Delphi - go the ST LOG SIG by typing "gr st" at the main menu. Enter the libraries with the "da" command.

Genie - go to the Atari ST roundtable by typing "m 475;3" and download files #7651 thru #7654.

and, various ST bulletin boards across the country.

ZMAG PUBLIC DOMAIN SHELF
by Ron Kovacs

The following listing is presented Ctsy of CompuServe Atari 8 SIG. This new column will spotlight files, news, and other information pertaining to Public Domain Software.

This week we focus on Rassilon. He has been writing software for a few years and makes it available on CompuServe Exclusively. We have not approached this person for an interview, but have listed his software which is currently available.

BLOCKS.DCM
Keywords: RASSILON COMPACTED BLOCK PUZZLE DISK

RASSILON'S BLOCK PUZZLE DISK! COMPACTED WITH DISK COMMUNICATOR V3.2 THESE ARE NOT EASY PUZZLES, BUT I HAVE LEFT MY LOWEST SCORES ON THE DISK. SEE IF YOU CAN BEAT THEM!
(c) Rassilon Software For Exclusive SIG*ATARI use ONLY!!!

BLOCKS.OBJ
Keywords: RASSILON BLOCK PUZZLE BINARY FILE

A BLOCK PUZZLE from Rassilon See if you can solve the puzzle. This is put here for the exclusive use of ATARI8 users only. Do not release this program to the public domain.

DANCE.DCM
Keywords: RASSILON SQUARE DANCE CHECKERS PUZZLE COMPACTED DISK

EASY GAME FROM RASSILON. SEE IF YOU CAN DO THE CHECKER SQUARE DANCE. A COMPACTED DISK USING DISK COMMUNICATOR V3.2. AS USUAL, A SELF-CONTAINED DISK.

EXCHNG.OBJ
Keywords: RASSILON EXCHANGE BINARY LOAD PUZZLE

ANOTHER PUZZLE FROM RASSILON. SEE THE DOC FILE FOR COMPETE INSTRUCTIONS. 'EXCHNG.DOC'

FF.DOC
FF.OBJ
Keywords: RASSILON BINARY GAME FOUR BY FOUR SQUARE 4X4

ANOTHER MIND BENDING GAME FROM RASSILON SEE IF YOU CAN PLACE ALL THE SQUARES WITHIN THE GRID. ADJACENT SIDES MUST HAVE THE SAME COLOR. SEE 'FF.DOC' FOR COMPLETE INSTRUCTIONS. FOR THE EXCLUSIVE USE OF SIG*ATARI USERS ONLY. NOT FOR PLACEMENT ON ANY OTHER BOARDS.
(c) RASSILON SOFTWARE 1988

KB29.OBJ
Keywords: RASSILON KELB MONOCHROME

THIS IS THE KELB GAME FILE MODIFIED FOR MONOCHROME MONITORS AS REQUESTED BY BLAQ [76046,1756]. JUST REPLACE THE KELB FILE ON THE UNCOMPACTED DISK WITH THIS FILE. ALL COPYRIGHTS STILL APPLY. ENJOY! RASSILON 29999 STOP:END

NITES.DCM
Keywords: RASSILON SIX 6 KNIGHTS PUZZLE COMPACTED DISK

ANOTHER GAME FROM THE DEVIOUS MIND OF RASSILON. THIS ONE IS THE CALLED "THE SIX KNIGHTS PUZZLE" THIS IS A COMPACTED DISK USING THE DISK COMMUNICATOR V3.2

PAIRS.DOC
PAIRS.OBJ
Keywords: RASSILON PUZZLE PAIRS BINARY LOAD

STILL ANOTHER PUZZLE FROM RASSILON. THIS ONE IS REAL EASY. (FOR THOSE WHO COMPLAIN THAT MY PUZZLE ARE TOO HARD, eh Maui Don?) SEE THE DOC FILE 'PAIRS.DOC' FOR COMPLETE INSTRUCTIONS.

POSPUZ.DCM
Keywords: RASSILON POSITION PUZZLES SIX DIFFERENT COMPACTED DISK

YOU DIDN'T ASK FOR MORE AND THE SYSOPS DIDN'T LET YOU HAVE MORE, BUT RASSILON NOW GIVES TO YOU 6 MORE PUZZLES. THESE ARE WHAT GAME THEORISTS CALL POSITION PUZZLES. DISK COMMUNICATOR V3.2 COMPACTED DISK. DOC FILES ARE INCLUDED. ENJOY!!!

SQUAD1.DCM
SQUAD2.DCM
Keywords: RASSILON INFANTRY SQUAD COMPACTED DISK 800XL 130XE MACHINES ONLY

RASSILON "INFANTRY SQUAD" DISK 1 COMPACTED WITH DISK COMMUNICATOR V3.2
THIS ONE CONTAINS THE GAME AND THE SCENARIO EDITOR. RUNS ON 800XL/130XE
MACHINES ONLY!!! (c) Rassilon Software For SIG*ATARI use ONLY!!!
PLAY COMBAT THE RASSILON WAY. I HAVE INCLUDED AN EDITOR SO THAT YOU CAN

Yes Keep posting Zmag...Also does it cost anything to call Delphi
if the call is local?(besides the 20.00 joining fee)

1443. Homepack & termcaps

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-14 20:58:22 UTC
From: hauck@limbo.uucp
Message-ID: <5652@pasteur.Berkeley.EDU>
Source record: 116597

I'm trying to use HOMETERM, part of HOMEPACK, to communicate with
several Unix-based machines and failing mserably. The problem is that while
HOMETERM emulates vidtex (a program in most termcap files), it displays 38
columns instead of 40 and 20 lines instead of 22+. This makes use of emacs or
vi (or any other text editor for that matter) impossible. I tried editting the
termcap entry and, while I could set it correctly in my environment, emacs
still insists on 40 columns, 22+lines, and vi just fails (it starts printing
in the middle of the screen and really messes up cursor motion). What I need
is one of the following:
1.) A good vidtex termcap that specifies 38 columns, 20 lines and
which emacs will accept (I changed the co & li entries and
it didn't work, so it's not that simple).
2.) A working termcap for 1030Express or the default 1030 modem program
(I have the 1030Express program, and since I own a 1030 I have
the program that's built into it)
3.) A way to tell emacs to shrink itself to 38 columns, 20 lines.
Thanks in advance.

>the XL is different -- though there's no reason why it should be).
^^

Actually, they are slightly different, though I never ran into a problem where
the difference mattered. The original 800 SIO port had 12V on one of the pins.
The 800XL puts out 5V on this pin. (This is because the 800 ran off of
an low voltage AC power pack and rectified its DC internally, whereas the
800XL runs off of a 5V DC power pack, and thats all it has to work with)

Could you please continue uploading the ZMAGS. The only way I can get them
is to call an East coast BBS (I'm on the west coast), and download them. Even
at evening rates and 2400 baud, that starts to get expensive.
Thanks in advance.

1447. more info on my interfacing problem..

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-15 19:54:00 UTC
From: BIW109@URIMVS.BITNET
Message-ID: <8809152000.AA28912@ucbvax.Berkeley.EDU>
Source record: 116601

The interface connects to the computer through the cart. port.
it uses the 7 low order address lines, and the CCNTL line for control
(addresses $D500 to $D57F are decoded). I used a design like this
because i want to build an interface into which cards can be plugged
into. The decoding logic works like this: A0-A3 are fed into one
74154 (4 to 16 line decoder), A4-A6 are fed into another one. Both
are enabled by the CCNTL (active low) line. All of the outputs of
the 74154's that are used (all on the first, only the first half on the
2nd - its high order input line is grounded) are inverted to obtain
active high strobes. The sixteen outputs from the first 74154 are
fed to 8 44-pin female plug in slots. The 8 outputs from the second
74154 are fed to one slot each (these are used to activate cards in
individual slots. The read/write line is passed to all slots in both
origional and inverted form. This was done so that when a particular
address on a card needs to be activated, a 3-input and gate can be used
(active high strobe) or a 3-input nand gate can be used (active low
strobe). Using this method, a card can be used in any slot, as long
as the program knows which one it is in (the relative addresses within
each slot are the same).
The data latch in question is a 74374 (i think.. I haven't been
home from school to look at it in the past few weeks), and acts on the
rising edge of the pulse. The timing problem that I was intested in
is how long is data valid for once it is placed onto the bus? Since
the latch acts on the rising edge of the strobe, i assumed that the
interface circuit must be taking too long. Since the 74154 is the most
complicated chip in the interface (if I remember correctly, it has at
least 4 or 5 levels of gates in it) I was thinking of using a high
speed version of the chip, assuming I can find one.
I hope this is enough info.. And thanks to anyone who can help..

if you have a good monitor i would suggest that you try VT10SQ. alot of people
prefer KERMIT over it, but if you have a good monitor the display on VT10SQ
is the best, it gives you a really good vt100 emulator, it wont show inverse
video but thats all it wont do for you. i've used it to play games on
a handful of different unix machines, it works on everything i've used it
on and works great with my xm-301. if you want a copy i might be able
to mail you a uuencoded copy of it. let me know.

I don't know for sure, but..... You can get "high" speed versions of the
74374 but I am not sure about the '154 in High Speed versions. I would
suggest usage of the HC series of devices, or if you can't find them,
LS series. 74LS and 74HC are both faster than standard TTL. LS stands for
Low-power Schottky and HC stands for High-speed CMOS devices. There is also
a version of the HC called HCT which will work best with TTL devices.
As you can see, the both of them should also be lower power than the
original TTL devices you have mentioned. I will check on the availability
of HC and LS versions of the 74154 and advise tomorrow.

1450. Re: more info on my interfacing problem..

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-18 00:36:33 UTC
From: rbrown@svax.cs.cornell.edu
Message-ID: <21105@cornell.UUCP>
Source record: 116604

The old Ataris run on the 1.79 MHz 6502B. The 6502 clock setup provides for a two part instruction cycle. Information placed on the bus is supposed to be valid for the duration of the appropriate part of the cycle (address during phi-1, data during phi-2). Phi-1 and phi-2 are approximately equal, each accounting for about 40% of an instruction cycle (with the other 20% taken up by transitions -- phi-1 and phi-2 are nonoverlapping, so there's some space between them). My documentation isn't where I can get at it, so I can't look up whether an instruction cycle takes 1/(1.79MHz) or 2/(1.79Mhz), but if we assume, for the moment, the former, then each phase of the cycle lasts about 223 nanoseconds (if the assumption is incorrect, then the cycle lasts some small integer (perhaps 2) times that long). As I said, this is not the final word, but I have confidence that it is no shorter than this.

1452. Glendale Atari Faire v.3 report(!)

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-18 20:45:50 UTC
From: rjung@nunki.usc.edu
Message-ID: <1408@nunki.usc.edu>
Source record: 116606
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

Well, it's now Sunday, 9/18/88, and the Glendale Atari Faire v.3 is over.
Here's a report, for those who are interested.
(If you're not interested, I suggest you hit "n" now:)

The Glendale Faire may have been a local event, but there were a few things
that net.people would be interested in:

* SPECTRE 128. It's _here_. NOW. David Small brought 200 copies out to
Glendale, and were they selling! The price is around $180 -- Make your
checks out to "Gadgest By Small". David (a very funny and fun guy) was
accompanied by his wife Sandy, his infant son, and a few friends.
And yes, I did see Hypercard running on an ST with my own eyes. David
also gave a humorous talk on the development of the Spectre, and
denies any plans to do an Amiga emulator for the ST or a Mac emulator on
the Amiga.

* 8-bit GEM. You want to revitalize your 8-bit Atari? Then take your picks:

Obviously, the biggest expectation in the 8-bit community is GOE
(Graphics Operating Enviroment). Yes, it was at the Faire, and yes,
Total Control Systems is selling them. They're not _shipping_ until
October, but you can order it now and get a discount. It looks like a
TOTAL clone of the ST's GEM (You can even hook up an ST mouse and run
GOE through it), and ran solid for the entire show. The author says it
will run 95% of all 8-bit programs. It comes on a ICD "piggyback"
cartridge, and takes up only 8K of RAM. There's supposed to be a library
of GOE routes, so other developers can easily make GOE calls and write
GOE products. Looks really terrific.

From the makers of _Celebrity Cookbook_ comes DIAMOND OS (aka ST jr,
depending on what time of the day you were at the booth). For $30, it's a
graphics interface that offers drop-down menus, windows, and other good
stuff (it doesn't _look_ like GEM, however). Reeve Software is promising
to release DIAMOND Paint, Write, Publish, and Programmer's Kits, for $30
each as well. It looks like it's disk based (I can't be sure),
but that's okay -- it can support up to 16 megabytes(!) of RAM.

* Genlock for the ST was demonstrated, in an open-board "final" version. JRI
says they're only waiting for the FCC, and then they'll ship. It's very
impressive -- An ST Cyberpain animation was being superimposed over a
music video, and the Genlocked result was being shown on both a standard
TV _and_ the SC1224 (how do they do that?). Ready to tackle the Amiga?

* Neocept, makers of FONTZ! and WORDUP (a great word processor -- an
unsolicited endorsement) were present. Nothing major was presented,

although the new version of WordUp, with numerous minor bug fixes, is expected to ship in two weeks. Registered owners will recieve a card in the mail about the upgrade procedure. Neocept also says they'll gladly take user input for improvements for their products -- Just drop them a line.

* Animation buffs like myself will be happy to hear that FILM DIRECTOR is finally being released. Epyx has gotten the rights to this two-year-old cel-based animation program, and it has been SUBSTANTIALLY improved (16 screens for cels, runs in 512K, better user interface, etc.). It should be out in October, and the $50 price tag gets you both FILM DIRECTOR and ART DIRECTOR -- A bargain! Maurice Molyneaux (a fun guy to chat with, a real professional artist) had a lot of input into the final user interface, and it shows. I can't wait.

* Megamax was also showing their soon-to-be-released Laser DB. It's a source level debugger for Laser C, and offers lots of features -- Source-code trace viewing, register value displays, breakpoints, multiple windows. If you liked Laser C, you'll want this.

* Codehead software was also demonstrating G+PLUS (I won't say anything about this, everybody and his cousin knows about it by now) and a new product called MULTIDESK. MDesk allows you to have 16 accessories of your choice in ONE menu slot. Even better, you can clear out and load NEW accessories at any time! You can also change the name MultiDesk registers itself on the menu, so you can have six copies of Multidesk -- each one with 16 different accessories -- for a mind-numbing total of 96 accessories avaliable simultaneously. Future products promised include FatBack ("A unique hard disk backup system") and CodeHead Utilities (A collection of programs and accessories).

* ICD was present and selling their cartridge-based SPARTADOS X. My friend bought a copy ($80, on a piggyback cartridge), and it appears to work just fine. Improvements include 1000+ files per directory, faster disk access, and built-in ARC/ALFCRUNCH support. The manual is still a preliminary copy, however, but ICD promises to send out the finals to registed owners when they become available. They also showed their FA-ST hard drive, available for 8-bit or ST hookup.

* Regent Software was selling copies of REGENT WORD II for the jaw-dropping price of $15 each -- Not $15 off, $15 EACH.

* Broderbund, surprisingly, was present. They were showing their new _Typhoon Thompson_ game for the ST (known on the Apple // as _Airheart_), as well as _Star Wars_ (imported from Europe; Broderbund is distributing). A version of _Karateka_ for the ST is promised, and "maybe" _Print Shop_, but little else. (The dealer was frank in why there was less Atari support -- "Our biggest market is the //gs"). No word on 8-bit support.

* And now, the word from Atari. Conspicuous by their absence, none of the Tramiel family showed up. Instead, we were treated to Sig Hartman, who promised us that "[1989] will be a critical point for Atari in the US

market". He also apologized for the lack of more ST's in America ("We had a limited number of Ataris, and we decided to put them in West Germany -- If we didn't, there would have been a hole for the Amiga or the Macintosh to get in"), and pledged closed attention to the end users, through user groups and public information services. Sig refused to "officially" confirm/deny the existence of the Atari Transputer, the 68020/68030 workstation/machines, or anything else -- except by saying "We're working on 7 or 8 products right now, and I can't say what they are." He did promise that 520/1040 owners will be able to get TOS and blitter upgrades, and that he will personally try to get more companies to produce 8-bit titles.

In a related vein, Federated promised the increased development of "compu-centers" in all their stores, and the possibility of offering in-store servicing for Atari products. They are also supposedly toying with the idea of carrying hardware accessories (boards, wiring, etc.) in the centers.

* Pledged to appear -- but never did -- were Data Pacific and Antic. Dealers who did appear, but didn't produce anything major, included Astra systems, Michtron, Migraph, and Seymour-Radix. Bill Skurski Enterprises was present, peddling copies of his "New User's Guide to the Atari ST" (book and videotape), as well as Best Electronics, Logical Choice for Computing, Mid-Cities Comp/Soft, and Comsoft.

Special thanks to John King Tarpinian, the local user groups, ACENET, and everybody else for makign the whole thing possible.

1453. Turbo CPU board for 8-bit

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-20 20:36:16 UTC
From: oaa@holin.ATT.COM
Message-ID: <115@holin.ATT.COM>
Source record: 116607

Just saw this on a BBS (Network Express 512-662-9765) and thought
it might be of interest.

Date: September 09, 1988
From: DataQue Software
P.O. Box 134
Ontario, OH 44862

To: All Atari 8-bit Developers, Users and Supportive Organizations

Re: Turbo Power without getting Burned!

***** PRESS RELEASE *****

There have been many mentions in the almost decade since the original
Atari 400/800 Personal Computers hit the dealers shelves about there
being a future upgrade to meet the user's needs, and new and more
challenging applications. Finally that upgrade is available.......
The Turbo-816 by DataQue, for the Atari 400/800/XL/XE.

DataQue Software is pleased to announce a powerful new upgrade which
was co-designed by Ron Shue, and Chuck Steinman. This upgrade will
be available in two forms. There will be a replacement CPU board for
the original 400/800 Computer system, and a plug in module for the
XL/XE series. In either case, there usually is no need for any
modifications to the existing hardware. The only exception to this
is with XL/XE systems which have their CPU soldered in place, which
will require the removal of the existing CPU, and the addition of
a standard 40 pin I.C. socket is suggested. Also included is the
Turbo-OS, by DataQue for use with the Turbo-816 CPU boards.

The Turbo-816 will not only increase the potential speed of the
computer, but also break the 64k memory barrier of the existing
systems. Not with the awkward paged memory, but with a fully linear
decoded address space of up to 16 megabytes. Benchmarks have put the
Turbo-816 into a performance range ABOVE many of the 'other" PCs/!!
Special memory boards will be available to take advantage of the new
extended addressing range. These will be mounted internal to the
computer cabinet, and in most cases require no hardware modifications.

And here is the amazing feature..... While adding all this power and
all this expanded addressing, the Turbo-816 for the Atari 8-bit
computer systems will maintain compatibility with most currently
available commercial and user written software. Using the Turbo-816
even those older programs will enjoy a speed increase!

The Turbo-OS is a replacement operating system for use with the Turbo-CPU which will release the 16-bit processor to its full power. Increased speed will be the most obvious change, but hidden in its code, will be an advanced new floating point library that will speed even the original Atari BASIC to new levels of performance. Again, on most systems it will be just a matter of replacing the existing ROM(s) with the Turbo-OS.

The future holds many more products for the Turbo-816 systems including:

1) a real-time multi-tasking operating system kernal
2) a new assembler-editor-debugger package which supports the new assembly level instructions and addressing modes
3) a new BASIC which will speed past the fastest of the current BASICs for the 8-bit machines
4) a new K&R compatible C development package
5) a new Turbo-GOS operating system (graphical based)
6) a developers development kit for new applications

The NEW Atari Turbo-816 should be available by November of 1988
For more information contact your local Atari Dealer or, write:

Subject: re: interfacing problem help

I think the CS2 line you describe is the same as the CCNTL line.
I got most of my information from Mapping the Atari (revised edition).
I am using an xl (the dreaded 1200xl, to be exact). All of the storbes
are ANDed or NANDed with the proper r/w signal, I didn't want strobes
being generated by accident.. Where is the phi2 (is this the second
phase of a 2 phase clock?) line that you mentioned? All Mapping the
Atari gives is a pin-out of the cart. port, giving names only for most
pins. If the phi2 is active low, it should be a simple matter to
invert it and and it with the write line, and make this result the
new write line (all strobes that the interface card generates are
active high). If I understand what you said correctly, the purpose
of phi2 is to indicate that the data bus is valid during write to
memory operations. Is this correct?
Thanks for your help!!

In my opinion the 1200XL was one of the best 8 bit machines that atari produced.
It is more compatable to the 800/400 OS than the 800XL and the 130XE. It
seems that the 1200 got a bad rap when it was introduced.

Official congrats to Mr. and Mrs. Larry Mihalik!!! A son arrived late afternoon on September 8, 1988. Best wishes from the staff of ZMagazine, ST-Report and AMy-Report.

Happy second birthday to Jessica Kovacs on September 9th.

Comdex is coming. We will provide as much coverage as possible. ST-Report will be covering with exclusive reports and we will print them here shortly after. Stay tuned for details.

SURVEY UPDATE

We want to thank everyone for responding to the Survey we printed a few weeks ago. We are looking into the suggestions and comments. If you missed the survey, don't fret! A special release will contain all of the survey questions along with a few more. More details on this special release next week.

=
Reader Commentary
=
by Dennis LaFontaine

I have several comments to make about the reader comment in Zmag iss #119, they are in the same order as the original letter is...

Yes, atari must do certain things, like advertise the REAL power of the ST, including on the spot credit financing (similar to the whirlpool plan or citi-bank method). Student discounts are on the way according to a spokesman that represents the dealer network head.

1. First off with color, can you say SPECTRUM??? (512 colors on screen at once). Can you say QUANTUM PAINTBOX??? (4096 colors on screen at once) Can you say DIGISPEC??? (24,386 colors on screen at once), Quantum even allows 32 colors in medium rez. All the above work on mmu's manufactured after early 1985, with no modifications to make inside, simply load and go! As for memory, I have personally seen an 8 meg ST in action, if at all possible, I will get the schematics on how to do it! Although the ST can do it, Atari still seems to be selling ST's under the 4 meg logo and the 16 colors logo. Both Digispec and Spectrum 512 can be obtained through Trio Engineering, or from The Catalog in Antic magazine. Quantum Paintbox is available from Eidersoft U.S.A Gray scaling is employed in many desktop publishing programs, it is also used by image scanners too.

2. Memory expansion without soldering is very easy. I wouldn't call two socket connections a 'TRICK' as you put it. Your statements about the mega is very valid though, I have still yet to see an expansion for their memory.

3. I am running a 520ST unmodified right now, after loading the raster fonts in, I have 398K free. Memory is not too much of a problem here. GDOS is great, it's about time it's available for the ST.

4. Good idea, bumper stickers are sort of like 'word of mouth' advertising. Atari would spend less money on stickers than they would on t.v. commercials.

5. I read an article about a dealer convention, student discounts were at issue, the general concensus showed everyone favored it, if this goes through, students will get approximately a 30% discount and will be eligible for the credit plan.

And a reply to the editors note, I have read an article about a prototype card box that connects to a 520 or 1040 DMA port and it acts exactly like the mega-st internal card slot expander.

@@
COUNTER POINT TO REBUTTLE
SWANSON'S SOAPBOX (huh?)
@@
by Rod Swanson

Jim, Sorry that you take life so dang seriously. Swanson's Soapbox was written with the Atari user in mind, not anyone else. It is meant for information and amusment. Computer slamming IS HEALTHY if done with a sense of humor and if it is restricted to OUR OWN AUDIENCE. I did not upload this to the AMIGA section trying to cause trouble. Sorry you do not see this the way I do. If you would have paid attention to the article you would have noticed that the Amiga points were by someone who once sold both machines, not I.

As for the JET review, I did not say anything that remotely suggests that WE SHOULD PIRATE the program. Please re-read the article more thoroughly again, without reading things into it that you imagine. Please focus your attention on the last 6 sentences!!. Again, sorry for offending a fellow 'ATARI' (?) user.
STya later - Rod.

PS. I will no longer pursue this subject so do not reply unless it is to yourself. No since in turning this thing into an argument.

Special Offer !!!
=

Special Offer From The SOURCE to readers of ST REPORT/ZMAGAZINE!

Until December 31, 1988, The Source is making a special offer to readers of ST REPORT/ZMAGAZINE who want to signup for an account with *no*membership*fee*! And with this offer, you receive a $60 credit applied to your first year of usage. To take advantage of this offer, you'll need your credit card, call 1-800-336-3366 (in Virginia 1-703-821-6666). Tell the operator who answers you would like to signup under offer #7BL0U60.

In addition, you may purchase The Source Manual for $12.95 (+$3.50 postage and handling). To signup for your account AND order the manual, tell the operator you'd like to signup under offer #7BM0U60.

++++++++++++++++++++++++++++++++++++++
FIRST CANADIAN ATARI USER CONVENTION
++++++++++++++++++++++++++++++++++++++

NOVEMBER 6, 1988

This is CANADA'S first and only Atari user convention this year. This convention is being put on and sponsored by "THE TORONTO ATARI FEDERATION"

user group. This group has over 500 members both in the TORONTO ONTARIO CANADA area and across the country as well as having associate members from around the world. We have a 40 meg 24hr bulletin board 416-235-0318 that has everything anyone would require when using ATARI SYSTEMS. If anyone wants more info re our computer show leave a message on the board and we will be in touch. If this is not convenient contact the people listed below.

This unique computer show is dedicated exclusively to ATARI COMPUTER SYSTEMS. This exciting new event promises to be jam packed with information, demonstrations, lectures and hands on work shops. One of the main exhibitors will be Atari Canada, showing off all the latest software as well as its new and innovative products. That's not all, there will be lots of retailers selling their wares as Special Low Convention prices, hardware and software manufacturers displaying their latest products, user groups talking to the crowds about Atari products and selling their PD software disks, lectures by knowledgeable speakers, seminars by prominent developers and even hands-on workshops where the registered participants can actually work on projects under the guidance of an expert. There will be something for everyone. From multi-player adventure games on the 8-bit to business applications for the Atari clones. So, if you are an Atari owner, or plan to be one or just looking for information, this is the place you will want to be.

THE FIRST CANADIAN ATARI USERS CONVENTION is being held at THE SKYLINE TRIUMPH HOTEL located just off highway 401 on Keele Street. NOVEMBER 6TH, 1988 from 10:00am to 6:00pm. (Special hotel rates available) Phone: 1-800-268-1332.

======================================
CompuServe PRIME/DAYTIME HOURS EXTENDED
======================================

Effective Sunday, Oct. 2, CompuServe's prime/daytime will be defined as
8 a.m. to 7 p.m. CompuServe's basic connect-time rates, which are the
same as prime/standard and standard/evening rates, are unchanged.

The one-hour lengthening of prime/daytime to 7 p.m. is to allow
CompuServe's definition of daytime access to be consistent with that of
its supplemental communications networks.

The CompuServe network surcharge will continue as one rate for all time
periods. For more information about CompuServe Information Service rates
and network surcharges, type GO RATES at any prompt.

NETWORK SURCHARGE ANNOUNCEMENT

Due to increased network costs, CompuServe will adjust network surcharges
effective Tuesday, Sept. 6. The CompuServe network surcharge will change
from 25 cents to 30 cents per hour. CompuServe basic connect-time rates
will remain the same.

Members accessing CompuServe from overseas through Computer Sciences
Corporation Infonet will incur a $50 per hour surcharge at all times.

The TYMNET and Telenet prime/daytime surcharge will increase from $10 to $12 per hour, though the standard/evening access surcharge will remain the same. Members now using TYMNET or Telenet are encouraged to check the online phones list (GO PHONES) for a CompuServe network number in their area.

COMPUTER BULLETIN BOARDS IN THE DEPARTMENT OF COMMERCE

The Economic Bulletin Board
==========
Operating agency

Office of Business Analysis
Office of the Under Secretary for Economic Affairs
U. S. Department of Commerce

Contents
Current economic news from DoC Economic Affairs(EA) agencies including press releases, economic indicators, official DoC summaries of economic news, information on how to obtain data tapes, and summaries of reports and studies produced by EA agencies. Also included are press releases issued by the Bureau of Labor Statistics.

Open to the public without charge. No preregistration required. Operated 24 hours a day, except when being serviced.

Telephone (202) 377-3870 or (202) 377-0433

Full duplex, no parity, 8 bit words, 1 stop bit, or Full duplex, even parity, 7 bit words, 1 stop bit 300 or 1200 baud. After connect, enter 1 or 2 returns to start

State Data Center Bulletin Board
==========
Operating agency

State and Regional Programs Staff
Data User Services Division
Bureau of the Census

Contents
News about new Census Bureau programs, Census publications, reference material for State Data Center personnel. For use of the Census Bureau staff and all State Data Center Components, including affiliates. Preregistration required - call information contact below.

Operated 24 hours a day, except when being serviced. Full duplex, no parity, 8 bit words, 1 stop bit, or Full duplex, even parity, 7 bit words, 1 stop bit 300 or 1200 baud. After connect, enter 1 or 2 returns to start

Information Contact:
John Rowe or Larry Carbaugh
Bureau of the Census

Population Estimates Bulletin Board
==========
Operating agency

Federal-State Cooperative for Population Estimates Population Division
Bureau of the Census

Contents
Information and news about population and demographic projections. For use by members of the Federal-State Cooperative for Population Estimates and members of the Federal-State Cooperative for Population Projections. No preregistration required.

Usual hours of operation 5:00 PM to 6:30 AM Monday-Thursday, 24 hour operation from 5:00 PM Thursday to 6:30 AM Monday. No preregistration required. Full duplex, no parity, 8 bit words, 1 stop bit. 300 baud. Telephone (301) 763-5225, After connected, enter "RUN" to start.

CMIC Electronic Bulletin Board
==========
Operating agency

Census Microcomputer Information Center, Office of the Director
Bureau of the Census

Contents
Microcomputer news, software and hardware reviews, public domain software, training programs for Census and Commerce personnel. General microcomputer users; primarily internal Census Bureau personnel. No preregistration required. Operated 24 hours a day, except when being serviced. Phone (301) 763-4576.

Full duplex, no parity, 8 bit words, 1 stop bit, or Full duplex, even parity, 7 bit words, 1 stop bit 300 or 1200 baud. After connect, enter 1 or 2 returns to start

Microcomputer Electronic Information Exchange (MEIE)
==========
Operating agency

The Institute for Computer Sciences and Technology (ICST)
The National Bureau of Standards
Department of Commerce

Contents
Information on the acquisition, management, and use of small computers. Other files containing sources of information on topics such as: conferences, Federal publications and activities, user groups, other bulletin boards, etc. General microcomputer users. No preregistration required.

Operated 24 hours a day, except when being serviced. Telephone: (301) 948-5718. Full duplex, no parity, 8 bit words, 1 stop bit, or Full duplex, even parity, 7 bit words, 1 stop bit 300 or 1200 baud. After connect, enter 1 or 2 returns to start. If you do not receive a carrier after two rings, you should hang up and call again.

Climate Assessment Bulletin Board
==========
Operating agency

Climate Analysis Center
National Weather Service
Department of Commerce

Contents
Historical climate information - daily, weekly, and monthly, heating degree days, weekly climate bulletins. Users generally are Analysts using historical meteorological data.

Operated 24 hours a day. Preregistration required. Call information contact below. Full duplex, no parity, 8 bit words, 1 stop bit.

Information Contact
Vernon Patterson
Climate Analysis Center
Telephone: (301) 763-8071

East Coast Marine Users Bulletin Board
==========
Operating agency

National Weather Service
U.S. Department of Commerce

Contents
Marine weather and nautical information for coastal waterways. Information includes data for bays and sounds, coastal waters, and offshore waters; tropical storm advisories; tidal information, and important weather, nautical, and fishing news. Data are primarily about the middle Atlantic region.

Users are Commercial fishermen and other users of coastal waters. The bulletin board is open to the public and free of charge. Users must preregister by calling information contact below. Information about similar bulletin boards for other regions may also be obtained by calling the information contact.

Operated 24 hours a day. Telephone (301) 454-8700. Full duplex, 8 bit words, 1 stop bit. 300 baud.

<[Holly] HS> Okay... welcome to our formal conference with some of our favorite Atari folks. You all pretty much know how this runs, but for those who don't.... if you have a question you'd like to ask, use the /RAI command to raise your hand and get into line. I will ack your raise with a private message and tell you who you'll follow so you know. I'll also try to give you some kind of warning when you're time is about to come up. When you're through with your question, please let me know via some kind of ack like GA (Go Ahead) or something... it makes things a little easier. Also, please remember that Neil and John are my guests tonight. Please treat them accordingly. *smile* In two weeks, we have Charles Johnson of G+Plus fame scheduled for a formal. I hope you'll make it...

<[Holly] HS> Let's start by having each of our guests introduce themselves and let us know just what they do at our favorite computer company... *grin*

<[Neil] NHARRIS> Sure. I've been with Atari Corp. for 4 years now, in a variety of roles, including publishing Atari Explorer, heading up PR, user group support, online support, advertising, product marketing, and sales for the east coast. My current assignment is with the Federated stores, specifically to bring them into the computer business. ga

<[John @ Atari] TOWNS> I have been with Atari Corp for almost a year now. I work in the Technical Support Dept and handle a wide variety of tasks. Everything from Online support to Shows to Technical Support on the phones during the day. It makes it quite an interesting job and I get the opportunity to meet alot of interesting people. ga

<[Mark @ Atari] MJANSEN> I've been with Atari for almost three years. I was the first technical support guy at New Atari, and then I moved into other things, like shows, West Coast Editing of Atari Explorer, Internal and Developer documentation, and various product development stuff, making sure New Things are Good Things. ga

<[David F.] D.FAIRWEATH1> Neil, does Atari have a definite strategy for increasing the ST's market share in the U.S. and will we see that strategy implemented before the ST becomes obsolete? Ga

<[Neil] NHARRIS> Before implementing any strategy, the issue we're facing is product availability. We have been living from hand to mouth for some time now. The DRAM chip shortage hurts, because we prefer to hold the line on pricing and that limits how many chips we can buy and how many machines to make. Right now, the lion lion's share of the computers are going to Europe,

to keep the hottest ST market in the world supplied. Once we can get more machines built, the US will get our fair share. At that point a strategy can be implemented. ga

<[David F.] D.FAIRWEATH1> O.K. but is there a defined strategy already in waiting for that eventuality? gaga

<[Neil] NHARRIS> Any strategy is time and market dependent. If we had machines to sell last year, we had a strategy ready. If we have machines this year, we have a strategy, but not the same one as last year, because the product is more mature now, with more and better applications, and because the market changes. Next year's strategy is likely to be different again. ga

<[David F.] D.FAIRWEATH1> O.K. one last point... I think that when the time comes you should push the fact that with hardware and software emulation the ST is 3-way compatible with Mac and IBM. GA that's all.

<[Neil] NHARRIS> I agree... as a selling point it is important. But when people buy the hardware, I know they'll find enough fine ST-native software so the compatibility issues are not a factor. ga

<[Rick] R.GRIDLEY> Mark, do you have any comments on the 3rd party development of the 16mhz board?

<[Mark @ Atari] MJANSEN> Not really...I'll have more to say when I see one.
<[Mark @ Atari] MJANSEN> Last I heard, it was still being worked on... ga

<[Rick] R.GRIDLEY> Neil, do you think that Atari owners are more concerned with the status of the parent company than other computer owners? ga

<[Neil] NHARRIS> I think it is reasonable to be concerned with the company which makes your computer, particularly in the case of a custom operating system. Apple users are concerned with Apple. I doubt that most clone owners care much about their company, they watch IBM. Overall, it is healthy, because the company steers the future development of the product to a large extent. Atari welcomes user inquiries and constructive criticisms, and we act upon them more frequently than is widely known. We love ya, honest we do. ga

<[Rick] R.GRIDLEY> Ok, (Grin) thanks and thanks to John with helping me with a problem about a year back. I am done thanks Holly

<D.D.MARTIN> huggs, Neil 1. Any truth to the rumor that the laptop will be available by the end of the year? 2. IBM or MAC compatability is a _major_ factor NEIL. The portability of office<-->home is a great selling feature. And _we_ have a choice of the _best_ that is available in software to do the job at hand. ga

<[Neil] NHARRIS> Any announcement of new hardware will have to wait for Comdex, sorry. Shipping times, too...

<[Neil] NHARRIS> I agree that it is an important selling factor, but we won't let that overshadow the need for continuing development of TOS

programs.] ga

<D.D.MARTIN> Atari users are prone to say.. I love _MY_ Atari, but I don't know if I love Atari.... We all know we have the greatest personal computer available...you folks at Atari do to.... so who's job is it to tell the others? ga

<[Neil] NHARRIS> Mainly ours, of course. But, from a BUSINESS perspective, which is the only perspective that our boss takes, you have to look at the return on any promoting we do. Right now, we sell every computer we make. We'd love to have enough computers to sell where we would have to advertise in order to move them all. So, in the meantime, the grass roots, meaning the Atari community, has the main role. ga

<[Darek] DAREKM> My question is a rehash of one already asked, but, why _not_ push the compatibility issue? The Mac, PC, and Atari 800 <grin> compatibility would interest a lot of people. Afterall, the 130XE looks very much like a 520, yet Atari rarely mixes ads of 8 bits and STs. However, you look in most Atari user group newsletters, and they mix the two computers all the time. Earlier tonight I was demoing my 8 bit drive to ST interface to a group of about 30 8 bit users (no ST users in the gruop) and about 1/4 of them indicated that they've thinking of getting an ST. When I showed them 8 bit software booting off an Indus GT, they all indicated they are _more_ interested. Wouldn't it be a great way to upload a lot of 520s and single sided drives, by having some kind of upgrade policy for 8 bit users to upgrade to the ST. I know you're short of DRAMs, but with the RAM of a Mega 4 you can unload 8 520s. ga oops, I meant to say "unload", not "upload"

<[Neil] NHARRIS> The Mega uses 1 megabit DRAM chips. The ST uses 256K-bit chips. So, making a Mega does not impact production of ST's at all. There has definitely been a solid trend toward 8-bit Atari users moving up to the ST. But to reiterate, it is difficult to justify from a business sense, promoting a product when we don't have enough to satisfy the current demand. ga

<[Darek] DAREKM> The 8 bit users indicated that one of the reasons that they'd like to upgrade is because the 8 bit software market is dead. I just see it as a great opportunity to get these potential ST owners before they get tired of waiting and buy a non-Atari 16 bit product. ga

<[Neil] NHARRIS> I don't know how to sell our chairman on giving a special deal to anyone, even our most favorite customers, at this time. ga

<[Norm] N.RECHTMAN1> Are there any plans to make a laser printer with more memory for 1040 users? and how about a desk jet copy? ga

<[Neil] NHARRIS> I think a better answer is for 1040 users to get more RAM. The reason for that is this: if you have RAM in the laser printer, it ONLY helps you when you are printing. If you put it in the computer, then it is available for other jobs as well. 4 megabytes comes in mighty handy when you are spreadsheeting, or doing a Cyber animation. I am not aware of plans for an ink jet printer from Atari, but again, we are not here to announce products tonight. ga

<[Norm] N.RECHTMAN1> that was just a suggestion. I would really like to see PC hardware addons ga

<D.D.MARTIN> Three cheers for Atari taking the bull by the horns and making plans to move production back to the US of A!!! Neil, can you tell us how things are progressing with the proposed plant in Houston? ga

<[Neil] NHARRIS> Well, our negotiating team is still terrorizing the folks in Texas. We expect some news shortly, but at the moment, nothing new to report at this time. ga

<[Dan] GRIBNIF> I have two questions: First, what is the current status of the CD ROM? ga

<[Mark @ Atari] MJANSEN> Most recent I heard is that we're trying to get some good applications together... Makes more sense than saying "Here's a CD-ROM player. Go to Tower Records and buy some CDs. Have a good time." It would be nice if there was something to _do_ with it first. ...so we're working on it. ga

<[Dan] GRIBNIF> Is that the only setback? Does it work with a Laser and HD yet?

<[Mark @ Atari] MJANSEN> Yes. And headphones. :-)

<[Dan] GRIBNIF> <smile>

<[Neil] NHARRIS> There is a driver for the CD ROM that lets it be read by TOS applications as if it were a really big drive. You can open it from the desktop and read files directly. So now it is a fairly simple matter of getting software which reads the databases on the CD ROM disks and does something with it. ga

<[Dan] GRIBNIF> (I was reffering to the rumored problems with other DMA devices)

<[Mark @ Atari] MJANSEN> I know several people with the setup you described.

<[Dan] GRIBNIF> ok, thanks. The other question is one that Neil probably saw in my letter to Info-Atari16... I was curious as to how normal users (not developers) will be notified of TOS 1.4...

<[Mark @ Atari] MJANSEN> Skywriting, blimps, dancing girls...(sorry, I couldn't resist.) and if they will also be provided with an "official" way of reporting bugs. ga

<[John @ Atari] TOWNS> <grin>

<[Mark @ Atari] MJANSEN> Well, it's like this... People will find out through magazines, etc. And dealers will know about it. The plan is to polish up a little program we've got here that is used for developers to submit bug reports, and release that to the public too.

<[Neil] NHARRIS> Through the dealers, primarily. And through all the communications at our disposal.

<[Dan] GRIBNIF> "through magazines, etc??" Atari Explorer is still reviewing things that came out 8 months ago as NEW!

<[John @ Atari] TOWNS> I believe that the information will also be published in the User's Group newsletter as well (Right, Neil?)

<[Neil] NHARRIS> Like I said, through all the communications vehicles at our disposal. I tend to think the Atari community is very well wired together. ga

<[Dan] GRIBNIF> ok, now THAT's more like what I wanted to hear <smile>
<[Dan] GRIBNIF> yes, I tend to agree. Sorry about that comment a second ago sounding a bit huffy. ga.

(sic. EOF)

1459. A more recent ZMAG

Newsgroup: comp.sys.atari.8bit

PUBLISHER'S DESK
by Ron Kovacs
~~~~~~~~~~~~~~~~~~~~

Originally planned for preview in this space was an article written by the Editors of Michigan Atari Magazine. I have cancelled this segment while I research and produce our official position on the matter. Stay tuned to these pages in the next few weeks for an indepth look at MAM.

Starting October 2, 1988, ZMAGAZINE will release issues on Sunday evenings. We will also debut a new section devoted to User Group Updates and news. Stay tuned for more details on this next week.

SCHEDULED RELEASES FOR OCTOBER

Issue #125 October 2, 1988
Issue #126 October 9, 1988
Issue #127 October 16, 1988
Issue #128 October 23, 1988
Issue #129 October 30, 1988

Due for release in October....Update of the official ZMAG/ST-REPORT BBS listing. If your BBS has not appeared, or you think you might be missing, Please send a post card with your BBS information and a phone number so we can contact you and give you your official ZMAG Registration number. The ZMAG 1988 Reader Survey is near completion. I need your address to send you the survey!! Please send that post card off today!! The survey is presently 8 pages long.

Enjoy your vacation John Deegan!

PRESS RELEASE 9/15/88

In an article called Atari News and Comment in the September Michigan Atari Magazine (MAM), editor Bill Rayl again blasted a non-participating local Michigan Atari users group for policies not in tune to MAM's liking.
~~~~~~~~~~~~~~~~~~~~

MAGIC, the eastern Michigan Atari users group who has stead fastly refused advances to join the MAM consortium, was sharply condemned for charging "50 cents to $1 admission" to attend a special meeting hosting Atari execs. "I was strongly misquoted by Mr. Rayl," says Sourcerer's Apprentice Editor Mike Lechkun. "I went out of my way to call Bill Rayl long distance to share and report this bit of local Atari news. I was shocked to see it turned into a negative slam against us (MAGIC)."

"I told his wife (and MAM co-editor) Pattie that MAGIC was asking for a donation to help defray costs of starting up another Atari fest effort [as well as to pay for the increase in space needed for the meeting]. It seems to me," commented Mike, "that MAM is allowed to rake in money for it's own ventures, but others trying to serve the Atari community are, in their words, 'tasteless'."

Mike concluded that he'd "be more than happy to make a donation in the Rayls' name if they couldn't cough up a couple of bucks!" It was MAM, over a year ago, who slammed then-non-participating club MACE when they proposed charging non-members to attend the monthly meetings. MACE was (and is) losing money rapidly by providing services to non-members who were sponging off the group. Because of the article, MACE was embarrassed into changing their newly adopted policy.

The members of MAGIC have always felt that a user group's newsletter helps to define and add personality and individuality to the club. The newsletter is the club's identity to the outside world. It is a shame that MAM feels that their viewpoint is the only valid one in Michigan, and that any other club's views are "considered extremely bad taste."

Quote from MAM, 9/88

Atari News and Comment

"In a move that can only be considered extremely bad taste, MAGIC is planning to charge 50 cents or $1 admission to attend this meeting [with Atari's execs]! The meeting takes place on their normally scheduled meeting night, and MAGIC's meetings are generally open to all. But, in this case, MAGIC proposes to charge admission from the very people they are going to need assistance from if another show will occur. MAGIC can't pull off an AtariFest on their own, but if any other clubs want to get involved at this first meeting, they'll have to pay to do so? Hopefully, MAGIC will change the tune before October..."

ATARI KILLS DETROIT VISIT

ATARI CORP.'s proposed visit to Detroit user group MAGIC has been cancelled. Sam Tramiel said that such a visit would "excite group members", but with no product to deliver and because we are right before Comdex, there's really nothing that could be said. ATARI has promised full support for a Detroit AtariFest, which the MAGIC group is still considering. Sig Hartmann commented that the November Comdex show would be "an opener to a revitalized U.S. market presence", and indicated a proposed resurgance after the first of the year. But as to not discourage those who would attend a large scale meeting from afar, Atari will not

make a local apperance until the show.

** NEWS BULLETIN **

Attention all persons that have a program being called "Master Cruncher" or any alterations of that. It seems that a group of pirates have edited out the Copyright notice and have claimed the program as there own. This Utility is not Public Domain nor a Pirate utility, it is a Commercial program that was going to be sold in The Federal Republic of Germany. There were plans to market it in the USA, but due to the massive spreading of the utility, there is no hope of making any kind of profit nor will there be any other such utilities produced due to these problems, it is not cost effective to try and track down who did this terrible thing, so you can just thank who ever the persons involed for screwing up the future of such useful utilities you might have had. Please notify all sysops or board operators that this file should be deleted from file sections and not posted again.

I was really surprised to hear that it was posted on 2 major commercial networks, I would have thought they would have questioned this utility because of no documentation or origin of source. I would have thought the sysops would be a little more responsible to there amiga comunity and check things that are questionable out first.

A final note, the version that seems to have made it's way all over the United States is still a beta version and has a Serious! bug in it, I do not accept any responsiblity for any damage caused by the faulty program. "it is not my fault everyone pirated it" I strongly suggest you uncrunch everything crunched with it or things might begin to happen you wish didn't. You have been warned of the problem. Please spread this file as fast as my program was spread to warn people against the possible destruction of all there data.

NEW BOOK ON COMPUTER VIRUSES
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Compute!'s COMPUTER VIRUSES

Author: Ralph Roberts
Price: $14.95
ISBN: 0-87455-178-1
On Sale: November, 1988
Publisher: Compute! Books, a Capital Cities/ABC Company

Why are the big computer companies keeping quiet about the problem of computer viruses?

``Over one percent, or about a quarter of a million IBM PC's and compatibles are already infected,'' says Larry DiMartin, president of Computer Integrity Corporation, the makers of the commercial viral protection program, Vaccinate.

Finally there's a book that shows why software and hardware manufacturers --in some cases selfishly and intentionally--have their heads in the sand. Finally there's a book that helps you protect your system from computer viruses. A book that answers the questions the industry has been ducking.

Like a biological virus, a computer virus can replicate itself and be spread (through the use of ``Trojan horse'' programs) from system to system. Trade a floppy disk with a friend and you may unwittingly be destroying all the data in your system, whether it's a single person computer or a large, networked system of 20,000 terminals. It's not even enough to have good backup--a timed release virus can also be in the backup disks or tape, destroying data time after frustrating time.

The destructive rampages of these small hidden programs from sick minds are not limited to ``high risk'' users who download indiscriminately from ``pirate'' electronic bulletin boards. AP and UPI reports in recent months have reported that such major institutions as NASA, Lehigh University, Miami (Ohio) University, ARCO Oil, Hebrew University in Israel, and others have had computer virus attacks.

Whether you are a single computer owner or a manager of a large area network, Compute!'s COMPUTER VIRUSES offers relief from the fear and the very real danger of a viral infection in your system.

Topics Covered:

* How your system can become infected (risky practices and how to practice ``safe computing,'' and minimize exposure.
* The history of viruses, including some infamous infections such as the ``Brain'' virus, the ``Sunnyvale Slug,'' the ``Scores,'' and the Macintosh ``Peace'' virus.
* How viruses work and what they can do to your system.
* The kind of programs that can hide viruses.
* How to detect a virus or viruses in your system and erase them.
* Protection from virus infection.
* Reviews and tips on viral protection systems, both commercial and public domain.
* Sections with specific protection information for IBM and compatibles, Macintosh, Apple, Amiga, Atari, and other systems.

Contents:

Your Computer May Be Sick!
History and Famous Viruses
How Viruses Work
Practicing Safe Computing
How The Experts Deal With Viruses

Corporate Initiatives for Data Security
(by Pamela Kane, President of Panda Systems)

The Case of the ``Gerbil'' Virus
(by Raymond M. Glath, President of RG Software Systems)

IBM and Compatibles
Macintosh
Apple
Amiga
Atari
The Only Good Virus is a Dead Virus.

LINE NOISE REVISITED
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Ctsy CompuServe Atari SIG

#: 47388 S2/CompuServe & BBSs 27-Dec-86 22:10:29
Sb: #Interlink
Fm: Jeff Rigby/Intersect Sof 74615,323
To: Dave Groves 76703,4223

I have never had the pleasure of taking apart a Courier 2400 but most
modems use the same input transformer (FCC Regulations).

Below is a schematic drawing of the Input transformer circuit:

```
----) || (------
Input from ( || ) output to
phone line ) || ( modem
----( || )-----
||
|| (------> 600 ohm Inpedance matching
|| ) < resistor
|| (------>

Transformer
```

You change the 600 ohm (blue black brown) resistor, to a lower value by
tacking a resistor in parallel. Try values from 1000 ohms to 600 minimum.
This is a quick and dirty method, it works by making the transformer less
efficient and therby reducing the sensitivity of the circuit. The resistor
is there to cause the input transformer to match the phone line (600 ohms)
impedance. When you have an impedance match you have maximum transfer of
energy. Choose the highest value resistor that gives the fewest errors.

****************** UPDATE **********************

17-Sep-88 09:21:43
Sb: #110696-2400 baud problem
Fm: INTERSECT Software 76004,1577
To: SYSOP*Dave Groves 76703,4223

The resister will reduce the sensitivity of the modem to incoming noise. If the problem is only periodic and does not get worse after warmup then this is the method to use. If it does get noisy after warmup then open the modem and look for an 8 pin chip with X2444 on it. It's an XR chip that sometimes causes the line noise problem at 2400 baud.

Since 2400 baud does push the Florida phone lines to the limit, neither method may work for you.

~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
CIRCUIT MAKER by Bill Pike (PAC)
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

My field of endeavour, that which I do when not using a computer, involves a lot of logic circuit design. Well anyhow I was going thru the local software store and happened to see a program on the shelf that immediately caught my eye. The name of the program is CircuitMaker and it was written by Ozzie Boeshans. The cost is $69.95, why not make it a even $70?. The program is published by ILLIAD Software.

For those who havn't used this type of program in the past, this includes until now me, this is the cats meow. No more breadboarding of circuits. No more burning out chips. No more tangles of wire, piles of parts, and general mess laying all over the place. Also, for those who are married, no spouse telling you to clean up your mess.

Version 1.2 of the program allows you to design various logic circuits on screen and TEST AND DEBUG THE CIRCUITS ON SCREEN. The program then will print the circuit on your Epson compatible printer. You can also go back to the last saved version of the circuit if you have made a mistake. The next version, 2.0, is said to allow you to specify and make a library of your own favorite IC's. Didn't I say that the program comes with 1 library of various logic gates and IC's? Well if I didn't, it does.

Here is what is in the library: All of the various types of gates including, a inverter, 2-4 input AND & NAND, 2 input ORs, 2 input NORs, and 2 input exclusive ORs, LED's, seven segment displays including the BCD to 7-Segment decoder, switches, two types of quad latches, 7474, 74138, 74151, 74168, 74169, 74109, and 74194 IC's.

There is a snap-to-grid feature so everything looks neat. The various logic devices can be rotated in 90 degree increments, you can label either vertically or horizontally. When you are wiring the circuit the curser is

accompanied, once you move out of the device area, by a set of full screen cross-hairs that show you where the wire will end up both vertically and horizontally if you extend it the full screen. This allows you to be much neater in the layout of wiring. There is also a dot placed where wires join so that you are sure of the connection. You can also move devices around or delete them if you decide that the location is bad. You are working in a window of the design, the window is approximately 15% of the working area. You can wire outside of the screen area.

I find that you should make a printout of just the device placement so you are able to easily find the devices not on screen when you start to wire. A zoom command would have been nice.

There are programmable pulse generators for signal inputs, each generator is independently programmable as to waveform and start time as well as well as when it starts. The speed is variable in common. There is a four input oscilloscope that can be used to check any four points in the circuit simultaneously.. You are able to either use a continous run or set for 5 or 10 cycles. The various wires show you the logic level on that wire by either being solid black (logic 1), dark dotted (logic 0), or light dotted (not active) as the test is running. If you are using a color monitor the colors of the lines change to indicate the same conditions. You are able to move around the screen during the run so you can see the functioning of the entire circuit.

There is a tutorial on fundamental logic circuit design included in the small 50+ page manual. The tutorial doesn't go into much depth and those who are unfamiliar with logic design should pick up a book on the subject as well as a TTL Device handbook so you can figure out just what the various chips are and what they require to work. The program doesn't go into microprocessor logic and if it did it should/would probably cost about 10 times as much, if not more.

This program is designed for the average designer and builder not for someone who does this for a living, he/she would probably have the $700 to $7000 version of this type of program and a main frame to run it on. This is a MUST HAVE program for anyone who designs logic circuits including those in college level logic design courses. It is also a must have for anyone who just does logic design at home for their computer interfaces or anything else, this is most logical (sorry about that it slipped out). So dig into your pocket and BUY THIS ONE.

********** SAM TRAMIEL IN CONFERENCE **********

The Atari Forums on CompuServe will be sponsoring a world-wide electronic teleconference with Sam Tramiel, President and Chief Operating Officer of Atari Corporation, on Monday, September 26 at 9:00 PM EDT. Your participation in this conference is welcomed and encouraged!

The Sam Tramiel Conference is going to be held in CompuServe's Electronic Convention Center(tm). The Electronic Convention Center(tm) was designed specifically for special conferences of this nature and can have as many

as 300 people participating simultaniously without causing the slightest speed decrease. In addition, the Electronic Convention Center(tm) offers the capability of holding a more structured conference, making it possible for you to ask your questions and be answered by Mr. Tramiel without any interruptions. Top performance is absolutely guaranteed! Lastly, the Electronic Convention Center(tm) offers additional conveniences (discussed later in this text) that will make your participation in this conference amazingly easy. If you've participated in other national conferences of this type before and have been underwhelmed at the way it was conducted and the performance of the service during 'heavy' usage, this conference is your opportunity to experience the communication power of a professional -quality global information network.

ACCESSING THE CONVENTION CENTER

As mentioned above, the Sam Tramiel conference will be held in CompuServe's Electronic Convention Center(tm) -- NOT the conference area of the Atari 16-Bit Forum. To access the Convention Center, type GO CONVENTION at any CompuServe command prompt.

When you type GO CONVENTION, CompuServe will display the following menu:

Electronic Convention Center(tm)

INFORMATION/RESERVATIONS
1 Instructions
2 List Conferences/Make Reservations
3 Review/Cancel Reservations
4 Conference Etiquette

Enter choice !

Choice 1 allows you to view the complete instruction guide for using the Convention Center. Choice 2 and Choice 3 allow you to list upcoming special conferences and any advance "reservations" (NOT NECESSARY FOR THIS CONFERENCE!) you might have made. Lastly, choice 4 provides some information on the etiquette followed by participants in an electronic conference.

On Monday, September 26, at 8:30 PM EDT (a half hour before the Sam Tramiel conference is scheduled to begin), the Convention Center menu will appear as shown above with the addition of menu choice 5 which will allow you to enter the Sam Tramiel conference. An example of how the Convention Center menu will appear from 8:30 through the end of the conference on September 26 appears below:

Electronic Convention Center(tm)

INFORMATION/RESERVATIONS
1 Instructions
2 List Conferences/Make Reservations
3 Review/Cancel Reservations
4 Conference Etiquette

JOIN CONFERENCE IN PROGRESS
5 Atari Sam Tramiel Conference

Enter choice !

All you will need to do is select choice 5 in order to join the conference. Once you select choice 5, CompuServe will prompt you to enter your name:

What is your name? John Doe

Enter your name and press a <CR> as shown in the above example.

If you enter the conference area before 9:00 PM EDT, you can chat briefly with other early arrivers until the moderated conference begins.

ASKING A QUESTION

Once the moderated conference begins, only the moderator and guest speaker will be allowed to openly communicate at all times. Other participants must signal that they would like to ask a question or make a comment by using the /QUESTION (or /QUE) command. Once you issue the /QUE command, CompuServe will add your name (in order) to the queue. When it is your turn to speak, CompuServe will beep your terminal and display a message explaining that it is your turn and you may now ask your question. If you attempt to openly communicate before it is your turn to speak, the Convention Center will send you a reminder that in order to ask a question or make a comment, you must enter the /QUE command and wait for your turn.

If you issue the /QUE command and change your mind about asking a question, you can enter the /UNQUE command to remove your place from the queue.

USING THE BUFFER

The Electronic Conference Center(tm) makes it possible for you to compose or upload your question or statement into a buffer area, followed by giving you the option of editing the text using standard CompuServe EDIT commands (explained in detail in EDIT.TXT, available in LIBRARY 1 of the Atari 16-Bit Forum). Then, you can send your pre-composed buffer when it is your turn to speak in the conference. Here are the commands you will need to know in order to use the buffer feature of the Convention Center:

/BUFFER EDIT - Brings you into "edit" mode where you can compose, ASCII-upload, or edit your text.

/BUFFER SEND - Send buffer to all participants.

OTHER COMMANDS YOU SHOULD KNOW ABOUT

The following list of commands are available to you in the Convention Center:

/BUFFER EDIT Edit text buffer
/BUFFER SEND Send text buffer
/BULLETIN Display short bulletin
/COMMANDS Show list of commands

/DAY Show date and time
/DISPLAY Change message display
/ECHO Show input as it is typed
/EXIT Exit the conference
/NOECHO Do not show input
/HELP Command help text
/NAME Change your name
/NOSEND Refuse private "send" messages
/OFF Log-off
/SEND Send a private message
/STATUS User/guest count
/WHO Show last speaker
/USERS List users
/LOOK Question status (how many people are in the queue)
/QUESTION Question request
/UNQUEUE Cancel a question

If you have any questions, please feel free to post a message to the Sysops of the Atari Forums. Otherwise, hope you found this introduction file useful and we're looking forward to seeing you at the big conference!

~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
8 BIT OWNERS UPDATE
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

There have been many mentions in the almost decade since the original Atari 400/800 Personal Computers hit the dealers shelves about there being a future upgrade to meet the user's needs, and new and more challenging applications. Finally that upgrade is available..... The Turbo-816 by DataQue, for the Atari 400/800/XL/XE.

DataQue Software is pleased to announce a powerful new upgrade which was co-designed by Ron Shue, and Chuck Steinman. This upgrade will be available in two forms. There will be a replacement CPU board for the original 400/800 Computer system, and a plug in module for the XL/XE series. In either case, there usually is no need for any modifications to the existing hardware. The only exception to this is with XL/XE systems which have their CPU soldered in place, which will require the removal of the existing CPU, and the addition of a standard 40 pin I.C. socket is suggested. Also included is the Turbo-OS, by DataQue for use with the Turbo-816 CPU boards.

The Turbo-816 will not only increase the potential speed of the computer, but also break the 64k memory barrier of the existing systems. Not with the awkward paged memory, but with a fully linear decoded address space of up to 16 megabytes. Benchmarks have put the Turbo-816 into a performance range ABOVE many of the 'other" PCs/!! Special memory boards will be available to take advantage of the new extended addressing range. These will be mounted internal to the computer cabinet, and in most cases require no hardware modifications.

And here is the amazing feature..... While adding all this power and all this expanded addressing, the Turbo-816 for the Atari 8-bit computer systems will maintain compatibility with most currently available commercial and user written software. Using the Turbo-816 even those older programs will enjoy a speed increase!

The Turbo-OS is a replacement operating system for use with the Turbo-816 which will release the 16-bit processor to its full power. Increased speed will be the most obvious change, but hidden in its code, will be an advanced new floating point library that will speed even the original Atari BASIC to new levels of performance. Again, on most systems it will be just a matter of replacing the existing ROM(s) with the Turbo-OS.

The future holds many more products for the Turbo-816 systems including:

1) a real-time multi-tasking operating system kernal
2) a new assembler-editor-debugger package which supports the new assembly level instructions and addressing modes
3) a new BASIC which will speed past the fastest of the current BASICs for the 8-bit machines
4) a new K&R compatible C development package
5) a new Turbo-GOS operating system (graphical based)
6) a developers development kit for new applications

The NEW Atari Turbo-816 should be available by November of 1988 For more information contact your local Atari Dealer or, write:

Thanks to Gary Duzan for posting the ZMAG issues, but one suggestion:

It might be better to include the ZMAG Issue # in the description line, just to make it easier to keep track of which issues are covered... for example, "A more recent ZMAG" could instead be "ZMAG #124"

1464. light gun?

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-29 00:47:48 UTC
From: wilmott@topaz.rutgers.edu
Message-ID: <Sep.28.20.47.46.1988.15825@topaz.rutgers.edu>
Source record: 116618

A while ago it was mentioned in this group that Atari had in fact decided to market the light gun seperately for all us 8-bit owners. I haven't seen it in any stores around these parts, and have yet to notice it listed in any ads in Analog, Antic or Atari Explorer. So my question is, when will it be available and for how much? Or if anyone knows of any mail-order places that are selling it yet, I'd appreciate their number/address. Also, what "XE Game Carts" are currently available for use with the light gun, and what ones are due to be released shortly?

-Ray

The only two currently out I know of are BUG HUNT and BARNYARD BLASTER (both from Atari Corp.). An interesting thing I saw at the Glendale Faire (but forgot to mention! Sorry!) was a near-finished version of Exidy's CROSSBOW for the XEGS/light gun.

Terrific game, all the kids were playing it both days. Seems to have all the original's features.

I've been off the net for about 4 weeks due to changing jobs, and I missed any reactions to the Mandelbrot program I posted. Did anyone try it? If so, what was the reaction? In the meantime, I added a bit of stuff to it, to allow easy close-ups to be shown using a joystick to select an area. It can get some pretty dramatic results.

1468. Using Kermit/65 with DOS 3.0

Newsgroup: comp.sys.atari.8bit
Date: 1988-09-30 12:06:00 UTC
From: PARSONS@KSUVM.BITNET
Message-ID: <8809301304.AA03617@ucbvax.Berkeley.EDU>
Source record: 116622

Although Dos 3.0 is perhaps the worst in the world, it was the Dos I was stuck with when I first purchased my 1050. I have obtained a partial copy (DOS.SYS and DUP.SYS ONLY/no convert utility) of Dos 2.5.
Problem: I have programs saved on Dos 3.0 disks that I would like to switch over to Dos 2.5 using Kermit/65 under Dos 3.0 to transfer programs to the mainframe at school and then using Kermit/65 under Dos 2.5 to get them back.

This sounds rather easy, but when using Kermit under Dos 3.0 after connecting and pressing 'A' as in Attention to start dialing out, the send data light on the modem goes on (constant, non-blinking) and the 'A' is repeated across the screen.
More: I am operating a vinilla 800, 1050 drive, P:R: Connection, and Anchor modem. I have scanned the limited Dos 3.0 manual, and it appears from the limited memory map that Dos 2.5 and 3.0 occupy the same base memory locations. All the other functions of Kermit are supported (ie rename, erase, dir) with no problems. The problem occurs in any terminal emulation mode and under any graphics display method. The only problem lies in dialing out (so far that is).

Any reason why 3.0, that opperates in the same memory constraints as 2.5, would cause such a bug in a perfectly healthy program? Anyone know how to solve this problem outright (besides getting a complete version of Dos 2.5 and just converting the Dos 3.0 files back to Dos 2.5)? Any suggestions on what may be happening? Anything?

Thanks, Parsons@KSUVM

Yes, I saw the same demo at the Summer CES. Crossbow was supposed to be out
the 3rd quarter (almost over). Another that is supposed to be out this
quarter that uses the light gun is Crime Busters (RX8104). It seems like
it should be quite interesting also if you like to fancy yourself as
Elliot Ness.

If you can get Kermit to work under DOS 3.0 this is a perfectly acceptable technique; however, I thought you might be interested in the fact that I once accomplished the DOS 3.0 - to - DOS 2.0 conversion using nothing more elaborate than Atari BASIC! Now if I can just remember HOW I did it...

As I recall, the program simply read the file-to-be-converted into a huge string buffer (I used repeated GETs, but a direct CIO call in ML would be cool too), under DOS 3.0; I was then able to soft-boot DOS 2.0 into memory without losing the BASIC environment, and write the string buffer back out using repeated PUTs. I was limited to the size of the string buffer, which ment a few COPY/APPEND's once I had the pieces on DOS 2.0, but it did work and I was able to get rid of DOS 3.0 for good.

Of course, I now find myself racking my brains to figure out how the &**&^(!*&^& I managed to boot 2.0 without turning off the machine or losing the BASIC environment. As I recall, it was very simple -- just a USR call to some system vector, given manually at the READY prompt -- and it did NOT work the "other way around" -- once in DOS 2.0 I could NOT similarly soft-boot into DOS 3.0 again. Had to turn the machine off and reboot with 3.0 every time I needed to get a new piece of file-to-transfer.

Anyway, if anybody here can deduce how I booted into 2.0 from 3.0, in BASIC, without losing anything, that might be the way to go as I'm sure with CIO calls it would be much faster than Kermit transfer! Plus you won't tie up your telephone line! :-) I *can* offer you my support that it DOES WORK; unfortunately for this instance I literally did GET RID OF my DOS 3.0 disk and cannot repeat my experiment on your behalf. I'll see if I can find it (borrow from friends) but in the meantime, Netters, what can we come up with?

Enjoy...

Chris Chiesa

In response to Scott McPheeters request for information about Delphi...

Delphi's basic hourly connect rate is $7.20/hour.

There is NO extra charge for 300/1200/2400 baud.

If you plan to use the system more than $24 per month, you can take "advantage of the Advantage Plan, where the connect rate drops to $4.80/hour, which makes it the *lowest* priced major information service, and this *includes* 2400 bau service. Telenet/Tymnet network charges are also *included* in the basic rate.

You can access Delphi through Telenet or Tymnet, or if you have PC Pursuit service, you can access that way, which means you are likely to be within a local telephone call range from Delphi.

For more info, call 1-800-544-4005

BobR (and *no*, I don't work for ANY online service anymore)

Really re: converting from dos3 to dos2

I thought there was a utility on the dos 2.5 disk to convert from dos 3 to dos 2. But I'm probably mistaken.

In any event... There was a program a couple years back in A.N.A.L.O.G that converted files from dos 3 to dos 2. I would guess this can be found on some BBSs as something like DOS3TO2.PRG.

I think Antic also had a similar program. Antic also published a program that turned your drive into a virtual 410 program (cassette) recorder. You would load from dos3. save onto a "cassette" disk. then boot up and save onto dos 2.

I am currently using a term prog which
doesnt allow me to emulate any standard
terms. (Amodem)
I have noticed that some people on the
net are using a term prog called kermit65.
As far as I understand this prog gices
you 80clmns and vt100. emulation.
Is this prog shareware ? If so can some
one send it to me or is the rumored atari
archive operating already ?
WIll it work on my setup (800xl , 1050 , xm301) ?

Thanx in advance,
-Edi

Edi, I think you're going to like this VERY much!

Yes, Kermit65 is available; I've sent it to several people already and can probably whip off a set of the relevant files to you with little trouble. The 64-dollar question is, can you pick them out of the Net and onto your Atari successfully? If you're using AMODEM, you can perform XMODEM and text-capture transfer as I recall; forgive me for asking what may seem obvious, but I've seen problems in this department: does your Net host system support XMODEM? How about "uudecode"? "Zoo" archiving? I'd want to send you a UUencoded Zoo archive containing the relevant Kermit65 files or, at the very least, a UUencoded binary of each individual file.

Anyway, your information is correct: Kermit65 gives you 80 columns, driven in either a GR.8-emulated 80-cols-at-once mode (a little hard to read at first but you get used to it) or a scrollable 40-columns-at-a-time "windowed" mode, plus emulates either a VT52 or VT100 (very nicely, I might add) or "dumb TTY", in addition to Kermit file-transfer. I ought to point out, though, that it does *NOT* perform any OTHER form of file-transfer, i.e. XMODEM or any of its family, nor text-capture. Nor can you "print screen" from within a terminal session. But I use it exclusively when talking to our University's VMS and UNIX mainframes...

As for whether it works with your setup, I'm not 100% sure, but am about 90%, that it WILL. There's a special modem handler required -- I think it's "SMARTT.COM," can anyone else doublecheck me on this? -- that makes the XM301 "look like" a Hayes-compatible modem to Kermit65. Or you could invest in an SX212, hehehe...

Let me know, via e-mail, which of the utilities (UUdecode, Zoo) you do have available to you, plus make sure you can download BINARY (not just Text) files from your host. If you can do Binary downloads and UUdecoding, I can send 'em to you. (Or, alternately, and I should have thought of this, if you have YAU (Yet Another UUdecoder) on your Atari, you can ASCII-capture the UUencoded files I send you, and decode them on the Atari. That might be easier.)

Chris Chiesa

A little while back a public domain runtime package was posted
to this group.

There was also mention that a program called BIGST was included in the
real runtime package. But Clint Parker also had it on his BBS.

I'd ask if someone could send me BIGST but I don't know if that's
"legal" or not. So, does anyone know the number to Mr. Parker BBS?

Thanks in advance,
Thomas M. Johnson

1479. WP & vugraph advice wanted

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-04 10:41:52 UTC
From: abrams@SMILEY.MITRE.ORG
Message-ID: <8810041041.AA02194@smiley.mitre.org.mitre.org>
Source record: 116633

I am considering shifting some of my text processing from a UNIX system to my Atari. I would like to describe what I am doing and solicit suggestions on how to achieve something similar on the Atari.

I am currently using troff to produce outline-format text and vugraphs from the same source. I do this will two different shell scripts which interpret a bullet command (i.e., .B1) to set margins and print one of the special characters (in this case a bullet, \(bu). I also use pic and tbl to include line drawing and tables; I have to scale the pictures and change font size sometimes to make them fit. I am willing to share my existing software with other UNIX users -- but that's not the purpose of this note.

For the Atari I am thinking about using the XLEnt First Word Processor (FWP), which I know how to use; or writing some BASIC programs which emulate the UNIX shell scripts. I also have Daisy-Dot II (DDII), which appears very useful for producing high quality printed output.

In the normal size text printout, I'm not sure how to incorporate line drawings and tables. There are undoubtly additional picture capabilities I might want to add, but I'm starting by thinking about what I presently use. My material is mostly technical, so line drawings have been quite satisfactory. I see that FWP allows me to include pictures using the ep command. Can anyone recommend software that I should use to produce line drawings and tables? Also, any idea what happens when such pictures are run through DDII?

I have even more questions about producing vugraphs. What's available to print 24 to 36 point size characters? Can I get presentation quality? (My standards are based on comparison with an Imagen laser printer.) Can I do some BASIC programming which will allow me to automatically generate continuation slides, or do I have to work a screen at a time? The same questions about tables and pictures also apply.

I would appreciate hearing from anyone with suggestions and experience. Partial answers and hints will be appreciated. I'll summarize the answers for the net.

Sincerely,

As reported in Issue #54 of ST-Report last week, Neil Harris has resigned
from Atari Corp. The following article appeared in the Atari16 SIG of
CompuServe. It is an opinion release by Dave Small. Following this
reprint, our opinion to this material.

#: 111539 S7/ST News/Reviews 25-Sep-88 12:33:50
Sb: #111449-#Farewell
Fm: David and Sandy Small 76606,666
To: Neil 70007,1135

**********N O T E**********
This is Dave Small's response to the announcement by Neil Harris
that he has resigned from Atari. For those who don't know Dave he is the
developer of the Magic Sac and Spectre 128: devices that emulate the
Macintosh computer on the Atari ST.
**********
```

This is really stunning.

If you think this is just another "Atari employee splits" note, consider:

1) Neil was the spearhead of Atari online. Here, Genie, Usenet, Delphi, you would find Neil. The support other than Neil has been fragmented to be charitable. (Due credit goes to Julius, though). Given the power of the online networks for marketing, and Atari's upper management completely missing that, this is big trouble.

2) Unless I am much mistaken, I'll guess Neil had Atari stock options. What does it tell you that he's leaving? I don't know how Atari stock could drop more (it's down to 6), but there's always a way. Maybe they can "un-split" stock to get it back to 12, *grin*. This means Atari is in big trouble.

3) Neil is the *only* effective public speaker Atari had. Atari did manage to waste much of it by forcing him to go say things that weren't so, or were only a little bit true. Neil gave innumerable talks and presentations to user groups at shows across the country. Just who is going to replace him? You don't find people like that easily, or sometimes, at all -- look at the number of corporations who have *no one* like that. This means Atari is in big trouble.

4) This happened right before the "big" CO here online with Sam. Big trouble.

5) This happened right before Comdex. Big, big, big trouble. Neil was one of the few people in an autocratic, 1950's-style management office that had any feel at all for reality. Now, what are we going to get? A repacked ST game machine with a laser tag pistol? A VCS / ST? You can bet that when it appears (if) at Comdex, there will be ghostly vapor surrounding it, the signal of a product not to appear for another year. Big, big trouble.

6) Atari has no grasp of the current US marketing situation; you can't stop support the instant the customer walks out the door with their ST and you cash their check. Atari tries to do that, of course. I remember well Alex Leavens getting canned for daring to support people who hadn't bought the developer's kit (among other peccadillos). "Business is war", when the people you are warring on are your *customers*, is dumb. We are in a service economy now; people expect *service*.

No? Atari top management held up release of the auto hard disk booter for a LONG time, claiming it would "cause a lot of tech support calls". The author, one Landon Dyer, is now at Apple, disgusted with Atari. He *wrote* most of the ST's BIOS; losing a lore-master like that is always very painful for a company.

7) Neil Harris has been with Jack T. a *long* time. What does it tell you that he's bailing out now? Do you think he would if he saw any hope of things changing? Do you think he'd go through the shock of job loss, moving, new company, etc, if he saw any chance at all? *Neil is not stupid*. Atari made him say stupid things, and folks like ST-Report

interpret that to mean Neil is stupid. Wrongo.

8) John Skruch -- whose word I trusted, a rarity at Atari -- is gone. Sandi Austin, who did those user group shows (remember?) is gone. Richard Frick, who was *instrumental* in getting the Magic Sac going, only to watch Atari's top management cold-shoulder it (Quote: "Why would anyone want to run Mac software when they have TOS?"), is gone. They've all left Atari recently.

9) Just who is going to get Atari publicity from folks like Jerry Pournelle anymore? Neil sold a lot of Ataris that way, and made the Tramiel people a lot of money.

10) Is it possible that Neil feels he's getting out before his reputation is ruined by an Atari crash? Already it's been damaged by things he had to say (Atari corporate policy).

11) The Comdex timing is especially significant. If Neil saw a future at Atari, it would be new products announced at Comdex. I have heard from other sources that Atari's top level management is now backing off from introducing ANYTHING new or interesting at Comdex -- wouldn't want to distract people from the ST, folks. Quote: "Atari's domestic market is Europe. The US is Atari's international market". Unquote. This makes Comdex look like a splash to me -- much like the May one, in the Abandoned Booth.

12) It says a LOT to me about working conditions at Atari that even Neil, who is pretty tough and good at political infighting, is leaving. If you've never seen a 1950's style autocracy, well, check it out. It is hard to stand (look at the number of people Atari has gone through at top management), clearly. Other companies don't tax their personnel like this; they realize that this is not the 1950's anymore, people are scarce and hard to find, and need to be *part of the company*, not just some slave-employee. Many other reports of working conditions at Atari make it sound like hell to work at.

13) If Neil doesn't think there's going to be profit in his stock options, you ought to be thinking about it too. (Again, this is a guess). It is possible that Atari is folding up; the collapse will just take awhile to reach the public.

14) Most ST developers are seriously considering jumping ship; a lot already have. Even Tom Hudson, arguably the best, is gone. Given how little Atari supports its developers (something Neil fought for) and gives online support (ditto), and that it could care less about selling into the US, it seems a waste of time to develop for the ST for the US market, when there's markets like Amiga, IBM, and Mac to develop for -- who have good documentation, people who aren't propeller-hat-heads online, and so on.

15) I think this marks the end of Atari US. The Spectre 128 is almost certainly my last ST product.

Dave Small Gadgets by Small, Inc.

OUR THOUGHTS??

After reading this message, a few thoughts struck me to be rather strange and almost shocking!! The bit about Neil being told what to say was just about the strangest thing I would expect. Neil spoke loosely about topics he either did not know about or put himself in the middle of topics by his own doing.

I am NOT defending Atari's position here, but you are way off base to elude ST-Report as a cause for Neil's apparent ignorance. From your comments, you DO NOT enjoy reading ST-Report. I fail to see the connection between the two.

To state that Atari is going out of business is another foot in your mouth. For whatever reason former employees of Atari have left is not meant to be used as an evaluation factor for business closing.

After reviewing the last six months of public chatter, originated from Neil Harris, I can say that either Sam Tramiel stood over Neil with an axe telling him what to say or he spoke on his own behalf. I wish to believe the latter since the previous could not be believable.

ZMAG UPDATE

Effective with this release, ZMag returns to Sunday evening release dates. One addtional note here, ZMag will make 40 column editions available with Issue #126 and all following issues.

Buried within this issue are sign-up offers for CompuServe and The Source, take advantage of these offers!

The Syndicate BBS is being scheduled for re-debut sometime in late October, early November, stay tuned to ZMag for the latest. I have been told that Ron Kovacs will return with an 8 bit system.

++++++++++++++++++++++++++++++++
ON TO BETTER THINGS by Ron Kovacs
++++++++++++++++++++++++++++++++

What will Atari do now?? My best hope is that Neil Harris will be replaced by a person who will report and give the community, Atari information which is in-line with current Atari policies.

I hope to see less opinion and more facts. Less banter about products not released and a NO COMMENT when appropriate! This might erase the VAPORWARE from the lipps of the Atari users.

Lets see more involvement with the developers, user groups and subscribers of the online services. Better communications with the public are sure to improve the Atari image. I feel respect of the community will provide Atari a better user base and more dollars!

Sam Tramiel has promised better things for 1989, lets hope so!!!

I am surprised at you Dave Small!

~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Data Pacific Newsletter
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

Msg#: 4622 *ATARI_ST* 09/02/88 17:16:00
From: MICHAEL SCHUSTER
To: ALL
Subj: DAVID SMALL/DP
Subject: New Data Pacific Newsletter

Data Pacific has released a new newsletter in the last few days that deserves a warning. It's full of distortions, half-truths, is misleading, and contains some flat false information. It's going to confuse a lot of people, so I'm trying to spread the word.

For instance, the newsletter contains columns from people who no longer work at dP (most of dP's staff quit in March-April, including me). It talks of a new tech person, "Mike", who does not exist and who always has been a pseduonym for Joel when taking tech calls.

More subtly, the newsletter implies that dP is having me look into a 128K ROM version of the Magic Sac. This is false; I have nothing to do with Data Pacific (except for one contract job -- version 6.1 of Magic Sac, in exchange for a LaserWriter). dP (Joel) agreed long ago to stop using my name to try to sell their products; they've broken their promise.

The newsletter says Dan Moore (dlm@druhi here) "worked overtime" to produce Mover 1.7. The truth is, Dan did Mover 1.7 for a flat $150 fee in July. He was paid by check after dropping off the disk; his bank later told him that Joel *had stopped the check*. In short, dP is selling a version of Mover 1.7 that they flat stole from Dan.

If you appreciate any of the contributions Dan has made to the ST world, such as the Twister disk format, Meg-a-minute backup, Protect desk accessory, and others, you could return him the favor by refusing to buy dP's disk until they remove Mover 1.7 from it, and letting them know why. Dan's had a rough month; he broke his hand recently, and is in a cast to his elbow (any get well cards sent via email would be greatly appreciated), by the way.

In my opinion, Data Pacific is attempting to present an image that things are as they were during the good days, while selling off as much stock as possible, with this newsletter -- then they're getting out. How else to explain them putting Apple's own Switcher and FONT/DA Mover on their "public domain" disk -- other than dP isn't planning on being around long enough for Apple to catch them (and rightfully so; Hertzfeld worked hard on Switcher).

I'd like it made clear I have nothing to do with Data Pacific anymore; I answer dP related questions out of courtesy to my old customers, and nothing more. The same is true for Dan Moore. The tactics Data Pacific is stooping to, in my opinion, to milk a little more money from the Magic Sac

before folding up are shoddy in the extreme, and I think it's a shame my name is still associated with this company. Hence, this note.

As for me, I have a new company, Gadgets By Small, Inc, and we're planning on releasing our first product (the Spectre 128) on Sept. 16, at the Atari Glendale Atarifest show. Since dP has broken it's word (again) to give me access to their customer mailing list, which I built, I can't put out the word about the Spectre 128 upgrade to the Magic Sac except by the networks.

For the record, and to answer a previous questions, I left Data Pacific in March of this year, when it became clear that (a) Joel was not going to honor our agreements, and (b) when I found out the FCC number being put on the Translator units had been forged, and Joel had no plans to ever FCC certify the unit. Believe me, I want no part of trying to slip one past the FCC. (Every Translator unit shipped bears this same false number.) I wouldn't be party to this; neither would Dan, when he heard. (Thanks to our friends from Supra for checking the number at the FCC BBS and telling us what had happened!)

I plan to carry on support of dP buyers with my new company, here and on other networks, as a courtesy to the people who shelled out money for the Magic Sac, but via a new company (Gadgets), as well as "push the envelope" further on Mac emulation with the Spectre 128 product. I don't want to advertise here on the net publicly; please drop me email privately if you're interested (hplabs!well!dsmall or dsmall@well); I don't think the local community would appreciate a few hundred "Yes, please send me info" notes here in comp.sys.atari.st.

Thanks for reading a rather long note; I plead that I'm used to getting paid by wordcount <grin>.

-- Thanks, Dave Small

~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
GLENDALE ATARI FAIRE
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

From: rjung@nunki.usc.edu (Robert allen Jung)
Subject: Glendale Atari Faire v.3 report(!)

Well, it's now Sunday, 9/18/88, and the Glendale Atari Faire v.3 is over. Here's a report, for those who are interested.

The Glendale Faire may have been a local event, but there were a few things that net.people would be interested in:

* SPECTRE 128.
It's _here_. NOW. David Small brought 200 copies out to Glendale, and were they selling! The price is around $180 -- Make your checks out to "Gadgets By Small". David (a very funny and fun guy) was accompanied by his wife Sandy, his infant son, and a few friends. And yes, I did see Hypercard

running on an ST with my own eyes. David also gave a humorous talk on the development of the Spectre, and denies any plans to do an Amiga emulator for the ST or a Mac emulator on the Amiga.

* 8-bit GEM.
You want to revitalize your 8-bit Atari? Then take your picks:

Obviously, the biggest expectation in the 8-bit community is GOE (Graphics Operating Enviroment). Yes, it was at the Faire, and yes, Total Control Systems is selling them. They're not _shipping_ until October, but you can order it now and get a discount. It looks like a TOTAL clone of the ST's GEM (You can even hook up an ST mouse and run GOE through it), it ran solid for the entire show. The author says it will run 95 percent of all 8-bit programs. It comes on a ICD "piggyback" cartridge, and takes up only 8K of RAM. There's supposed to be a library of GOE routes, so other developers can easily make GOE calls and write GOE products. Looks really terrific.

From the makers of _Celebrity Cookbook_ comes DIAMOND OS (aka ST jr, depending on what time of the day you were at the booth). For $30, it's a graphics interface that offers drop-down menus, windows, and other good stuff (it doesn't _look_ like GEM, however). Reeve Software is promising to release DIAMOND Paint, Write, Publish, and Programmer's Kits, for $30 each as well. It looks like it's disk based (I can't be sure), but that's okay -- it can support up to 16 megabytes(!) of RAM.

* Genlock for the ST was demonstrated, in an open-board "final" version. JRI says they're only waiting for the FCC, and then they'll ship. It's very impressive -- An ST Cyberpain animation was being superimposed over a music video, and the Genlocked result was being shown on both a standard TV _and_ the SC1224 (how do they do that?). Ready to tackle the Amiga?

* Neocept, makers of FONTZ! and WORDUP (a great word processor -- an unsolicited endorsement) were present. Nothing major was presented, although the new version of WordUp, with numerous minor bug fixes, is expected to ship in two weeks. Registered owners will recieve a card in the mail about the upgrade procedure. Neocept also says they'll gladly take user input for improvements for their products -- Just drop them a line.

* Animation buffs like myself will be happy to hear that FILM DIRECTOR is finally being released. Epyx has gotten the rights to this two-year-old cel-based animation program, and it has been SUBSTANTIALLY improved (16 screens for cels, runs in 512K, better user interface, etc.). It should be out in October, and the $50 price tag gets you both FILM DIRECTOR and ART DIRECTOR -- A bargain! Maurice Molyneaux (a fun guy to chat with, a real professional artist) had a lot of input into the final user interface, and it shows. I can't wait.

* Megamax was also showing their soon-to-be-released Laser DB. It's a source level debugger for Laser C, and offers lots of features -- Source-code trace viewing, register value displays, breakpoints, multiple

windows. If you liked Laser C, you'll want this.

* Codehead software was also demonstrating G+PLUS (I won't say anything about this, everybody and his cousin knows about it by now) and a new product called MULTIDESK. MDesk allows you to have 16 accessories of your choice in ONE menu slot. Even better, you can clear out and load NEW accessories at any time! You can also change the name MultiDesk registers itself on the menu, so you can have six copies of Multidesk -- each one with 16 different accessories -- for a mind-numbing total of 96 accessories avaliable simultaneously. Future products promised include FatBack ("A unique hard disk backup system") and CodeHead Utilities (A collection of programs and accessories).

* ICD was present and selling their cartridge-based SPARTADOS X. My friend bought a copy ($80, on a piggyback cartridge), and it appears to work just fine. Improvements include 1000+ files per directory, faster disk access, and built-in ARC/ALFCRUNCH support. The manual is still a preliminary copy, however, but ICD promises to send out the finals to registered owners when they become available. They also showed their FA-ST hard drive, available for 8-bit or ST hookup.

* Regent Software was selling copies of REGENT WORD II for the jaw-ropping price of $15 each -- Not $15 off, $15 EACH.

* Broderbund, surprisingly, was present. They were showing their new _Typhoon Thompson_ game for the ST (known on the Apple as _Airheart_), as well as _Star Wars_ (imported from Europe; Broderbund is distributing). A version of _Karateka_ for the ST is promised, and "maybe" _Print Shop_, but little else. (The dealer was frank in why there was less Atari support -- "Our biggest market is the gs"). No word on 8-bit support.

* And now, the word from Atari. Conspicuous by their absence, none of the Tramiel family showed up. Instead, we were treated to Sig Hartman, who promised us that "[1989] will be a critical point for Atari in the US market". He also apologized for the lack of more ST's in America ("We had a limited number of Ataris, and we decided to put them in West Germany -- If we didn't, there would have been a hole for the Amiga or the Macintosh to get in"), and pledged closed attention to the end users, through user groups and public information services. Sig refused to "officially" confirm/deny the existence of the Atari Transputer, the 68020/68030 workstation/machines, or anything else -- except by saying "We're working on 7 or 8 products right now, and I can't say what they are." He did promise that 520/1040 owners will be able to get TOS and blitter upgrades, and that he will personally try to get more companies to produce 8-bit titles.

In a related vein, Federated promised the increased development of "compu-centers" in all their stores, and the possibility of offering in-store servicing for Atari products. They are also supposedly toying with the idea of carrying hardware accessories (boards, wiring, etc.) in the centers.

* Pledged to appear -- but never did -- were Data Pacific and Antic. Dealers who did appear, but didn't produce anything major, included Astra systems, Michtron, Migraph, and Seymour-Radix. Bill Skurski Enterprises was present, peddling copies of his "New User's Guide to the Atari ST" (book and videotape), as well as Best Electronics, Logical Choice for Computing, Mid-Cities Comp/Soft, and Comsoft.

Special thanks to John King Tarpinian, the local user groups, ACENET, and everybody else for makign the whole thing possible.

~~~~~~

ST X-Former Update
by Darek Mihocka

Always wished there was an easier way to transfer files from your 8 bit floppies to the ST? Are null modem cables just not your style?

Finally! Move all your Atariwriter and other word processing files to the ST. Graphics screens and icons. Database files and spreadsheets.

It's ready! About a month ago I first announced the development of an interface to allow STs to communicate with 8 bit disk drives, like the 810, 1050, and XF551 drives. I will start shipping them on Oct. 3.

The interface consists of a cable that connects between the ST and the disk drive, and allows for two way disk and file transfers, with the proper software. This software is in several forms, for different users.

Because the cable does not necessarily require that it be used with the ST XFORMER emulator, it is going to be sold separately from any software.

To be fair to current registered users of the ST XFORMER Atari 8 bit emulator, they will have first crack at the cables. To qualify, you must have already registered your copy of Xformer 2.1 ($20). (I have your names on file, so don't cheat!) The cable will then cost you $20 US (or $25 Canadian). In conjunction with the release of the cable, a new version of the ST XFORMER will be made available on Oct. 1, and as usual, will be made available on Compuserve, Genie, and Delphi. XFORMER 2.2 will have all of the features of version 2.1x with the added capability of using the cable to boot the Atari emulator directly from an 8 bit drive. (Even from copy protected disks, although not all of them)

The few users who have just registered recently for version 2.1 are being kept on file until October and will receive version 2.2, since other enhancements have been added to the program.

This leaves tens of thousand of ST and 8 bit users who do not qualify. For you folks, the cable is $25 US (or $30 Canadian), and of course, you will have access to ST XFORMER by modem or by registering. Registration for the XFORMER is $20, but since I am eager to get more users, you can get the cable, XFORMER 2.2 and the printed manual for $40 US (or $45 Canadian).

For those people who want the cable to transfer files, but are not interested in the emulator, I have a utility for you! The XFORMER Quick
~~~~~~

Transfer Utility allows you to grab files of entire disks and transfer them quickly. Those of you who saw the several megabytes of 8 bit ANALOG files that I recently uploaded to Compuserve and Genie may be interested to know that each floppy disk took under two minutes to transfer to the ST (the same time it takes to read the disk into a sector copier on an 8 bit). Imagine how quickly you can transfer your entire 8 bit library to the ST (where, one day, you will decide to run it on the emulator).

The current limitation is that the disks must be in DOS 2.0 format to allow the files to be extracted, although if you plan to use the emulator, the disks can be formatted by most DOSes, and even be boot disks.

I am still working on several other major utilities, including one that allows most other ST programs to read and write directly from the 8 bit disk drives, and more. When it is ready, I will let everyone know.

Also in the works is a 520ST version of the emulator that supports the interface (an enhanced ST XFORMER JUNIOR).

To order, send a MONEY ORDER or (no personal checks from the US!!! because Canadian banks are not too swift at processing them) to me:

Darek Mihocka
310-D Bluevale St. N.
Waterloo, Ontario N2J 4G3
CANADA

Thank the almost 100 registered users of ST XFORMER who motivated me (and demanded!) that this interface be created.

Pricing is as follows.

Registered users:

US $ Canadian $
ST XFORMER Interface Cable 20 25
ST XFORMER 2.2 update
(with Quick Transfer Utility) 10 10

(note, users who just registered in the last couple of weeks will get the update free in October)

Non-registered users:

US $ Canadian $
ST XFORMER Interface Cable 25 30
Quick Transfer Utility 10 12
ST XFORMER 2.2 registration 20 20 (shareware)
All 3 of the above 40 45

Please add $3 per order for my postage and shipping costs.

I would like to get users groups involved in this. I have visited about half a dozen local user groups and found a lot of interest in the emulator

and interface. The problem was that many of the users, both 8 bit and ST, do not have access to Compuserve or Genie, or even a modem, and so, were unaware of the existense of the emulator. Therefore, I would like to give discounts to large orders placed through user groups, because it helps me. Call me by voice for details.

Oops, did I mention the BBS yet? As mentioned last month, I am going to put up a support BBS shortly. I am writing it from scratch, but it is coming along. It will provide additional support for all Atari users, by providing information about the emulator and interface, and files for downloading,

ST XFORMER BBS / voice support (519)-747-0386

BBS: 12am-6am EST (sometime soon)
voice: other times

During other hours, I will answer by voice and provide support for the products.

Thanks again for your support.
=-=-=-

So far, very few people have joined the "bandwagon". Those who have will no doubt recognize their concerns as they are included in one area or another of this issue. As more persons join in the production of "Goin' South", the "causes" with which we concern ourselves will gain in scope and variety. So it you finish this issue with the feeling that it is a bit "one-sided" (or maybe "lop-sided"), remember, YOU can make that difference!

.....Send all mail, inquiries, and comments to "ED.SOFT".....

DOES IT BOTHER YOU THAT...

...you can go to the beach to get innoculated?
...you can beg money to run a political campaign, but in some cities you can't beg for food?
...you can be asked to prove you are innocent without being charged with a crime? (Some Americans are willing to say, "If you're innocent, what do you have to fear?", and thereby give-up the principal of being "innocent until PROVEN guilty".)
...in today's conservative political mood, "liberal", the American Civil Liberties Union (ACLU), and the Congress of Industrial Organizations (AF of L / CIO) are considered un-American?
...some religious leaders preach the ultimate treason, replacing the Constitution? (with what does not matter)
...some school systems refuse to allow "meditation time" for students?
...the two leading killers in our society, alcohol and tobacco, are protected by our government (by us). (Most children can name (and correctly spell) more of these products than they can (name and spell) Presidents.)
...the world (planet Earth) is on the verge of being overdosed by people population and people waste (and we're NOT talking toilets)? (Some groups feel birth control in any form is evil.) (Some groups feel "Western Civilization" MUST keep growing [in numbers]...even though "the West" produces most of the pollution in the world.)
...we want stiffer penalties, but we're NOT willing to pay the tab (taxes for more jails), so... (Some judges refuse to sentence cocaine dealers to jail for less than 5 pounds!) (Some jail systems are mass early-releasing inmates [If this keeps up, it will mean "The more crime, the SHORTER the time in jail per criminal"; don't think that's the way it should work].)
...there are hard-working (if they could find a job) people who go unemployed and homeless while ex-convicts make large amounts of money from their books and lectures?
...our infant mortality rate in among the HIGHEST in the industrialized world?
...our "middle class" elderly lose their life's savings to our "old age system"?
...advertisements have to carry "small print" in order to "tell the truth" (at least, "the truth" in a legal sense)?

If you think any of the preceeding "statements" are erroneous, PLEASE WRITE IN, leave a note at ED.SOFT; we'll be glad to answer your questions.

If you think you have a good "Doesn't it bother you that..." situation,
PLEASE WRITE IN; we'd love to share it with our readers.

11-Audio Input
12- not connected
13-Interrupt

Those two ports, a hole to adjust the volume, a telephone jack, an on/off switch, a dc power jack, and some indicator lights are all you get with this baby. Not really a lot to play with, no nice confusing dip switches to messup, also no nice dip switches to set dtr to always on.

Therefore to use Shadow backgound Terminal Program to it's fullest some method must be found to keep the DTR line voltage up during a system reset, so that you can get out of that game or heaven help us, crash, so that you can keep from loosing the file you are downloading.

The way to do this is to get an RS232 jumper box and connect pin 1 on SX-212 to pin 1 on st, and connect pin 2 to 2, pin 3 to 3, 5 to 5, 7 to 7, 8 to 8 and 22 to 22. Then make up a jumper wire that will reach from the jumper box pin 20 on the modem side to the no.5 pin on the 8-bit SIO port of the SX-212. to get a connector to fit on the pin of the SIO port you can tear apart a Radio Shack 276-1538 that cost $2.49 for one connector to solder on the end of the jumper wire, or hand roll one from an old HO guage track connector like I did.

Once this is done you will have to use +++ ath0[return] to hang up the modem, but it wont hang up when you don't want it to.

If anyone knows a way to make the SX212 have DTR always on by sending an s register command, Please leave me E-mail on Genie to: T.LAMPARTY1

Connecting the Tandy 3 1/2 inch drive to the Atari ST

To connect the Tandy 3 1/2 inch external drive to the ST, the following connections must be made:

ST Floppy Port Pin Function Tandy Drive Pin
1 Read Data 30
2 Side 0 Select 32
3 Ground Any Odd
4 Index 8
5 Drive 0 Select 10
6 Drive 1 Select 12
7 Ground Any Odd
8 Motor On 16
9 Direction In 18
10 Step 20
11 Write Data 22
12 Write Gate 24
13 Track 00 26
14 Write Protect 28

These connections may be made using two methods. The easiest would be to take an ST drive cable, cut off one connector, and connect the cable directly to the 34 pin header on the drive itself. This will directly bypass the circuit board inside the Tandy drive case. The major drawback to this method is the fact that you will not be able to unplug the cable from the drive.

The other method, although more complicated, will allow you to utilize the 30 pin edge connector mounted in the back of the Tandy drive case. First remove all paths leading to the upper pads of the edge connector and all paths on the bottom side that do not lead to ground. Wire all connector pads on the bottom side together so that they all are connected to ground. At the point where the ribbon cable from the drive is attached to the circuit board, wire the necessary connections to the pads of the 30 pin edge connector. Remember, any odd number pin on the drive itself is ground, so connect one to the bottom connector pads of the circuit board being modified. Be sure to note each connector pad you are using, and it's corresponding function. Now attach the ST drive cable to a 30 pin edge plug in accordance with the wiring accomplished on the circuit board.

Once wiring has been completed, place the jumper on the drive mechanism to the A0 position. If your computer won't recognize the drive, try the A1 position.

The drive requires 12V 230mA and 5V 240mA for power. I use a standard PC power supply using either connectors P10 or P11.

Weatherman's Wisdom-October 1988
By:Lawrence R. Estep

INTRODUCTION

This month I begin what I hope will become a monthly feature of this newsletter. In this article each month, I will review the new and old (classic) Atari 8-bit programs, talk about rumors, Online services news, etc. I will also try to keep you up to date with the latest happenings in the world of Atari itself. I hope you enjoy this article each month, and I would greatly appreciate any comments, questions, complaints, or suggestions you have about it!

NEW APPLICATION PROGRAMS FOR THE 8-BITS

In the past few months, several new application programs for the Atari 8-bits have been released. Among them, are Newsroom from Springboard, and Video Title Shop from Datasoft/Electronic Arts, which we will review this month!

Newsroom
Springboard Software,Inc.
Catalog Sales
7808 Creekridge Circle
Minneapolis,MN 55435-9805
Suggested retail price:$39.95

Equipment Needed: Atari 800XL, 65XE, or 130 XE & Dot-matrix printer.
Optional Equipment: Joystick, 2nd Disk drive.

Yes, Atarians! Finally, we have got a program for publishing purposes for the 8-bit! After a long write-in campaign by Antic magazine readers, Springboard finally has developed Newsroom for the Atari, along with 3 data disks ($39.95 for all).

I have found Newsroom a very simple program to use, and it produces great looking results! The production of a newspaper is simple. You begin in the banner area to create the banner for your paper (the area on the top of the first page that includes the title, date, etc.), and then you proceed to the photo lab, where you choose the graphics you are going to need, and you take electronic photos of them. After taking your photos, you then proceed to the copy desk, where you add text, and arrange your panels to be placed on a page.

After you have arranged your panels, you then go on to the layout area, where you arrange your pages. The final step in the production is the press, where you do the actual printing of the paper. An inexperienced user can produce a 3-page paper in a little over an hour, if they read the directions before they begin.

Here is what I thought of the program:
~~~~~~

-Advantages: Use of joystick to speed layout procedure, ease of use, etc.
-Disadvantages: Slow speed without the use of joystick, inability to convert and import other graphics into the program, limitation of 2 small,and 3 large fonts,etc.
-Overall rating: ***+- (3 1/2 stars-slightly above average- This program definitely needs to be revised upon users suggestions to include the option to import other graphics, and fonts,etc.).

Video Title Shop
Datasoft
19808 Nordhoff Place
Chatsworth,CA 91311
(818) 886-5922
Suggested retail price:$29.95

Requirements: Atari 64k+ home computer, compatible disk drive, TV or monitor, joystick, blank formatted single-density disks, VCR, videotape.

Video Title Shop for the 8-bits is a rather unique program that allows you to use your computer to produce titles and introductions for your videos, or credits for your productions. This program really does not need a lot of explaination, so we will just get right to the point!

Video title shop lets you use several different fonts from large to small, which you can add to Micropainter (62-sector) pictures, either included on the disk, or your own, to produce a stunning graphics display for your home video productions. This program includes the Micropainter program & instruction guide, along with the Graphics Companion I disk, which includes over 30 full screen canvases. An additional disk is available for $14.95 with more graphics.

Here is what I thought of the program:
-Advantages: Special effects abilities, ability to use other pictures in production, ease of use,etc.
-Disadvantages: Inability to take advantage of 130XE extra memory, very slow in loading procedure of graphics, etc.
-Overall rating:***-- (3 stars-Average- as with Newsroom, this program needs to be revised upon the users suggestions, but I believe that both programs are worth the money, and that we should buy, and support them!)

HIGH-TECH MOVES

High-Tech Expressions, makers of Printpower, Awardware,etc. has moved! Their new information is as follows:

High-Tech Expressions
584 Broadway
Suite 1105
New York,NY 10012
(212) 941-9703

IN OUR NEXT ISSUE

<*>Information on 130XE Nickelprint keyboard problem/exchange program.
<*>High-Tech Expressions programs reviewed
<*>And much,much more!

AEL TALK

There will be a special halloween program disk for the 130XE, and regular 8-bits, at the October AEL business meeting in the PD library for $3. For more information contact Jason Dickens, or Lawrence Estep. We also hope to have special holiday disks for Thanksgiving and Christmas in the coming months.

Also,watch for the NEW edition of THE BBS GAZETTE, coming to the Atari Scene!, and CompuServe soon! It will have complete details on the changes in THE BBS REPORT, and much, much more!

1481. SpeedScript 3.0

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-05 03:27:00 UTC
From: JEO065@ALBNY1VX.BITNET
Message-ID: <8810050458.AA12157@ucbvax.Berkeley.EDU>
Source record: 116635

Hello all,

I just finished typing in speedscript 3.0 out of Compute May 1985
vol. 7, No. 5. And I was wondering has anyone used it? If so, could
you give me a clew as to how to exit it without turning off the computer?
I am using it on an Atari 800xl with Spartados and a percom dd/ds drive.
I would like to use it with cc8, but I cant get out of it. I read through
the article and I see only one way to get back to dos, and that is if you
are useing os/a+ which I dont have.. Any suggestions? Please reply to
me as I am not able to get the news group here.

Jim Otto..

1482. CC8 Documentation

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-05 18:23:43 UTC
From: smk@cbnews.ATT.COM
Message-ID: <1449@cbnews.ATT.COM>
Source record: 116636

[This is a repost of the V2.3 CC8 documentation with notes appended
for V2.3b, the last posted version of the compiler. I won't be
reposting the compiler itself (no time to figure out how to get it
to this machine). - Steve]

CC8 DOCUMENTATION

This compiler is an upgraded version of the Deep Blue C (DBC) compiler
which supports more features of standard C and is much faster. It
generates the same kind of pseudo code as DBC and ACE C and can
be used with either's linker and runtime engine. I recommend using ACE
C for its speed and expanded features. This document gives a brief
overview of the extended features of the compiler along with its
limitations.

This document is not intended as a C tutorial, nor is it intended
as a tutorial for DBC or ACE C. Features such as assembly language
protocol, built-in routines, and floating point depend solely upon the
type of linker and runtime system you are using, and NOT upon this compiler.

PREPROCESSING

CC8 supports all preprocessor functions except for #line. This
includes macro functions, #ifdef, #ifndef, #if, and #undef. In addition,

o #include files may be nested (currently only 2 deep)

o no restriction on placement of comments

o the TAB character may be used as white space.

o predefined symbols __LINE__ (replaced by current line number) and
__FILE__ (replaced by current file name).

o #ifdef, #ifndef, and #if may be nested (5 deep maximum).

Caveats:

- "bizarre" usage of #define macros may not work as expected (or
at all)

- in the "skipped" section of an #ifdef-#else-#endif group, comments
are not processed. Thus it is not a good idea to "comment out"
#else's or #endif's.

VARIABLE DECLARATIONS

CC8 supports more complex type constructions than DBC or ACE C, e.g.,
pointers to pointers. In addition, the types struct, union, and enum

have been added and variables can be declared static.

o multidimensional arrays may be declared.

o functions may be declared as returning char, int, or pointer
to anything. Pointers to functions, arrays of pointers to
functions, etc, may be declared. Note: a pointer to a
function must now be used correctly:

(*pf)();

not

(pf)();

o variables declared as type "enum x" are really declared as
type "int"; the name "x" is ignored. Note that user
assignment of numbering scheme is implemented, e.g.,

enum colors $(red = 2, white = 0, blue $);

assigns red = 2, white = 0 and blue = 1.

o external array declarations of the form

extern int array_name[];

are now valid.

o in expressions, the sizeof and type cast operators may be
used.

Caveats:

- no float/double declarations (but a limited floating point is
available when ACE C's linker and runtime engine are used)

- all struct/unions must have a tag name

- all global symbols, struct/union tags and components are drawn
from the same name pool.

- no bit fields

- identical declarations of a variable neither cause an error
nor do they work reasonably. For example,

int a; int a;

will silently declare "a" twice and confuse the linker.

COMPILE TIME EVALUATION OF CONSTANT EXPRESSIONS

CC8 supports a limited form of compile time evaluation of
constant expressions. A constant expression is defined as
any expression containing integer constants, character constants,
sizeof, or a constant expression separated by one or more operators

in one of the following groups, "|", "^", "&", "==", "!=", ">> <<",
"+ -", "* / %", or prefixed by one of the unary operators, "-",
"!", "$-". Evaluation follows normal rules of operator precedence
and can be overridden by parentheses. Examples:

x = 12*24 + 13; => x = 301;

x = 12 + 13 + y; => x = 25 + y;

x = y + 12 + 13; => x = y + 12 + 13; (1)

x = y + 12*13; => x = y + 156; (2)

x = y + (12 + 13) => x = y + 15; (3)

1. compiler "gives up" after finding non-constant 'y'.

2. '*' is in a different precedence group than '+' and thus "12*13"
appears to the compiler as a separate expression.

3. Parentheses force compiler to treat "12 + 13" as a subexpression.

Constant expressions may be used in array declarations, initializers,
and #if.

INITIALIZERS

CC8 supports initialization of global variables of type char, int,
pointer, array, struct/union, and enum. The syntax is a subset of that
allowed by standard C.

Rules:

1. Simple types (char, int, pointer) can be initialized by
a constant expression. The constant expression must not
be enclosed inside $($). Absolutely no type checking is
done. The definition of constant expression is extended
to include:

o address of static variable
o static array names
o function names
o "character string"

2. Aggregate types can be initialized by the following
construct:

$(init-element-1, init-element-2, ..., init-element-m $)

a. if fewer initializers than elements appear, the rest of
the aggregate is initialized to zero.

b. if the number of elements of an array is not specified,
then it will be set to the number of initializers.

c. a character array may be initialized by a string.

Examples:

```
int x = 23*22;

char *p = "hello";
char q[10] = "hello"; /* q[6] ... q[9] are set to '\0' */

int f();
int (*pf)() = f;

/* array bound set to 5 */
char *weekdays[] = $( "Mon", "Tues", "Wed", "Thu", "Fri" $);

struct x $(
char *symbol;
int value;
$);
struct x tab[] = $(
$( "word1", 4 $),
$( "word2", 8 $),
$( "word3", 13 $)
$);
```

Caveats:

- local variables cannot be initialized (bad programming practice anyway)

- unions cannot be initialized (properly, that is)

GOTOS AND LABELS

CC8 supports the dreaded goto statement and labels. Note: the compiler cannot distinguish between labels and local variables.

ERROR HANDLING

Error messages are printed in the typical Unix C fashion:

file-name, line #: error message

In addition, the line causing the error is printed. Note: if the error occurs near the end of a line, the compiler will usually flag the next line.

This compiler, like DBC and ACE C, does not know how to intelligently recover from syntax errors. For this reason, the compiler will halt compilation after 8 errors.

The compiler no longer exits directly to DOS on fatal errors (e.g., too many errors) so that the user may jump directly to an editor using the command line feature described below.

I would appreciate knowing if the compiler hangs after finding an error or a certain sequence of errors.

INTERNAL LIMITS AND TABLE SIZES

Lest we forget this is a 48K 8 bit implementation of C, here are some of the more important limits:

1. 7000 bytes of "global space" -- shared by:

- macro definitions
- each unique non-macro symbol name (15 bytes + length of symbol)
- global symbol type info

2. 256 bytes of "local space"

- local symbol type info
- only 128 local symbols may be declared.

3. A source line may not be longer than 254 characters after macro expansion. WARNING: this limit is not checked!

4. An expression cannot generate more than 512 bytes of p-code instructions. An expression violating this limit would be ridiculously huge. WARNING: this limit is not checked!

5. 512 bytes of "string space"

- This table was 3000 bytes in DBC and probably ACE C too.
- A way around the size constraint is to use initializers:

```
char dummy1[] = " ... ";
char dummy2[] = " ... ";
...
```

6. 2300 bytes of stack space

The compiler has been written to conserve stack space, so stack overflows should be a rarity. This is fortunate because -- WARNING: this limit is not checked! Stack overflow will overwrite screen memory (but it's possible compilation will complete normally).

7. #define macros may have up to 128 arguments.

CC8 uses memory from MEMLO to MEMTOP and locations $480 to $6FF. MEMLO must not exceed $2BFF.

SPEED

CC8 is much faster than DBC and slightly faster than ACE C (15% - 30% depending on type of program). Compilation time is affected most by the presence of #defines. You should expect compilation times of 15 to 30 seconds for small programs, and up to 2:00 for large programs with many #defines. Larger source files are possible, but run the risk of running out of internal table space. Some sample times:

Program Description	SC	ACEC	DBC
238 lines, no #defines	58	80 (1)	551
same, one #define	66 (2)	77 (1)	-

482 lines + 222 #include'd
many #defines + comments 107 - -

Note: these timings were made on an 800xl with a 1050 running DOS 2.5
with write verify on.

(1) I can't explain this anomaly.

(2) The reason one #define makes so much difference is that the compiler
takes advantage of the zero #defines to skip part of the pre-
processing phase.

COMMAND LINE FEATURES

For users of DOS' that take a long time to reload (such as DOS 2.X), a
way to load and run files directly from the command line has been
provided.

o ^L<RETURN> runs file called "D1:LINK.COM"
o ^Lfilename<RETURN> runs file called "filename"
("D1:" and ".COM" default)
o ^E<RETURN> runs file called "D1:EDIT.COM"

Note this feature is in its infancy.

1. The control characters print as their equivalent graphic characters.

2. ^L runs the ACE C and DBC linkers, and ^E runs SpeedScript. Nothing
else has been tested.

3. "Theoretically" the load routine understands INIT addresses.

MISCELLANEOUS

Switch statement handling has been reworked. The last clause need not
end in "break", "continue", or "return". In addition, the "default"
clause need not be the last (this was a bug in DBC). On the down side,
you are limited to 100 "case"s per switch statement, and switch statements
may be safely nested only four or five deep. I'll wait until someone
complains before I attempt to fix this.

More efficient code is now generated for the && and || operators.

Local variables must be declared at the beginning (not just anywhere
as in DBC) of compound statements. However no two local variables
declared inside a function may have the same name (this is a
departure from standard C). Variables declared with a storage class of
"register" are the same as "auto".

All C reserved words are recognized by the compiler. Thus a variable
cannot be named "float" or "entry."

Characters with the 8th bit set that are not part of character constants,
strings, or comments will cause the compiler to crash.

FASTC.COM should work on CC8 output.

I have been told that the compiler also works with the LightSpeed C linker and runtime engine.

FUTURE

1. Improve error handling

2. Add ability to pass files to compile in command line for SpartaDOS and compatible DOS.

ACKNOWLEDGEMENTS

Thanks to Harald Striepe and Marc Appelbaum for their beta testing.

Thanks to Mark VandeWettering and Greg Koolbeck for their input.

cbnews!smk

The following is a list of fixed bugs, enhancements, and known problems:

Bug fixes:

1. Empty expressions in for statement accepted, i.e.,

for(;;;) $($)

2. Constant expression are now valid after "case", i.e., "case 2*3." (fixes "case -1:" problem)

3. "*a" if a is an array no longer generates an error.

4. A function argument declaration of "type var[]" is now converted to "type *var." Previously, the compiler generated bad code which caused a lock-up when the resulting program was run (e.g., programs using "getname()" in ACECIO.C).

Enhancements:

1. The expressions "a[x]" and "x[a]" are both valid and equivalent provided one of x or a is a pointer or array.

2. structs without explicit tag names are now legal, i.e.,

"struct $(.... $) y;"

3. The compiler now recognizes the keywords "short" and "long." Note that "int" = "short" = "short int" = "long" = "long int" = 2 bytes. "Long" declarations produce the warning "long == short."

4. The compiler now recognizes the keyword "unsigned" and
will generate unsigned comparison code for <, <=, >, or >=
when one or both operands are unsigned.

Caveats:

- You'll have to write your own routines to print these
correctly (no %u in ACE C or DBC printf).

- I'm not sure *, /, or % work properly on unsigned numbers.

Known problems (send mail or post if you want to add to the list):

1. Not all escape sequences recognized by ACE C are recognized by
CC8. (\u, \d, \l, \r, \e)

2. Compiler doesn't like "register x" although it will accept
"register int x." Note that "register" doesn't do anything
special anyway.

Yes, SMARTT is indeed the handler you need. Unfortunately, last time I looked
there was a small address overlap between SMARTT and KERMIT, and I was not
able to get a copy of SMARTT based at a lower address. On the other hand
I think I remember someone reporting that the combination works, so perhaps
nothing serious is getting trashed.

If needed I can send a copy of SMARTT.

1484. XF551 Drive <> Flight Sim II incompatible

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-06 16:11:25 UTC
From: conklin@eecae.UUCP
Message-ID: <12295@eecae.UUCP>
Source record: 116638

A word of warning to you folks considering a purchase of the XF551 and or Flight Simulator II from Sublogic. These two products are NOT compatible. I have tried multiple copies of Flight Sim II (fortunately, friends have it too) and my XF551 simply wont boot them. It's not just a matter of booting the disks. Switching back to my 810 drive, they (of course) work just fine.

If I boot with the 810, and then switch drives, it will fail anyhow, on the next disk access.

It's my impression that this has something to do with a protection scheme on the disk. Being that my 810 has trouble reading the high tracks on diskettes (which is why I wanted a decent drive in the first place) I _need_ to be able to use my good drive.

Being as I started flight school last week, I'm rather miffed.

I have yet to call Sublogic about the problem. But I will.

Source record: 116639

Hello again.

Wow, what a response! I've received quite a number of requests for Kermit65 for various hardware configurations, and since I have the whole darn thing sitting here, all UUencoded and ready to go, I may as well post it. I'll wait a respectful period in case someone wishes to present a compelling reason NOT to post it (size, maybe?), and also to make sure that it actually works with the various configurations -- ONE friend here is having trouble using Kermit65 with the SX212 connected directly to SIO, and yet another friend with, as far as we can tell, the SAME hardware, is NOT having the problem, so we're trying to track it down before posting it so that we can tell YOU how to not have problems.

If someone out there is DEFINITELY SUCCEEDING in using direct-SIO-connected SX212 with RVERT212 for Kermit file-transfer, please send me E-mail so we can compare notes. Likewise if you are using this configuration and NOT succeeding!

Thanks,

Chris Chiesa

There was a problem with the protection scheme used on early copies of
Flight Simulator II that would keep it from working with the XF551.
Sublogic is aware of the problem and can provide you with a fix.

I am told the same thing can apply to some copies of the "Scenery Disks."

The September issue of Current Notes (the Washington area user group
magazine/newsletter) had a review of the XF551 by Curt Sandler. He had
the same problem with FS II that Terry did. It turns out that Atari
set the disk drive speed on the XF551 at 300 rpm instead of the old 288
rpm speed. This is ok for most software, but FS II is very sensitive
to drive speed. This may be part of their protection scheme. They didn't
offer any solution, but it would seem to me that the speed could be
changed to 288 rpm. With this information, maybe you could experiment
some and report back to the net.

From your comments it sounded as though you might not be aware of the excellent uuencode/uudecode software available for the Atari 8-bitters. It is entirely practical to download uuencoded files to your Atari and decode them there, if you don't have kermit or xmodem available.

I wrote a uudecoder awhile ago in BASIC with assembly language subroutine to do the dirty work. It can be shipped over the net in .LST format and downloaded with an ASCII file capture program. Then you can use it to uudecode whatever you like. UUDECODE.LST (or .BAS) is so fast that speed is not much of a reason to wish for something better. But if you get tired of booting up in BASIC to use it, you may want to download John Dunning's assembly language uudecoder and matching uuENcoder, uudecode them using my BASIC version, and then retire the BASIC program to be used only for helping other people get started.

Let me know if you need copies of UUDECODE.BAS or "YAU", Yet Another Uudecoder, the assembly language version.

Also, there is another pretty decent vt100 emulator called OmniCom, which is Shareware -- the author requests $10 if you plan to keep using it. I can forward or post a copy of that also if anyone needs it.

Source record: 116646

Jim Otto asks about SpeedScript 3.0... I started typing it in a couple of years ago, and then found out about OMNIVIEW and OmniWriter, which is a much-enhanced version of the old SpeedScript. Most of the commands are the same, but 80 column screen displays make it just like a "real" word processor.

I suggest you look into OMNIVIEW for your 800XL and run OmniWriter, which comes on a disk included with OMNIVIEW (which is a replacement O/S ROM).

I have gotten a lot of mail about how they enjoy these magazines. Also, there have been several complaints about having ads and opinions like the ones in the mags posted to the net. There has been enough dispute to prompt me to take some kind of action. I have decided that since USENET is a public domain network and we live in a democratic society, I will put it up to a vote. If you have any interest either way please send me private mail with the following information:

Which publications do you read? (ZMAG/ST Report/both/none)

Would you rather have it/them posted to the net or mailed? (net/mail)

Would you like to be added to a future mailing list? (yes/no)

Please keep answers brief and put any comments at the end. Please note that our mailer here at Vax1 isn't perfect. There is a chance that it may not be able to find some of you. Hopefully, this will solve the problem.

1494. Wanted - Atari and Amiga info in Rochester, NY

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-11 02:03:57 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <4261@bsu-cs.UUCP>
Source record: 116648
Cross-posted to: misc.wanted,comp.sys.amiga,comp.sys.atari.8bit

I am soon to move from my school habitat of Muncie, IN, to my former hometown and future workplace of Rochester, NY. I have an Atari 800, an Atari 800XL , and an Amiga 1000 computer. I've had pretty good support (service, other users, information) out here, but am very out of touch with the corresponding support in Rochester.

I would like to receive information on BOTH types of system (Atari 8bit, and Amiga of any flavor), i.e. stores that carry associated products -- hardware and software, user groups and clubs, BBS's, individual enthusiasts in the area, and whatever else one can think of.

I recently visited Rochester for a few days, and stopped into Leon's Computer Mart, where in the Good Ol' Days one could find virtually ANYTHING, but the situation there was pretty pitiful -- one small, whimpering shelf of old stuff comprised the entire Atari AND Amiga collection.

Now, come on, gang, if a small town in Indiana (great support in Marion) can support both these brandnames, surely a supposedly-sophisticated (last time I checked) city "back East" ought to be able to. Please E-mail me ASAP, as I am not a regular reader of this group and will be reading my mail by long-distance telephone, if at all, after the 22nd !

Thanks in advance, and am looking forward to quite possibly MEETING some of you when I get to Rochester!

I've been trying to write a decent program to display the M-set since the first
Scientific American article, but then I found a really nice one from Analog
(I think). It allows you to zoom in on any section of the displayed set with
a joystick. Real nice.
I liked yours because it used graphics 10 though, the program I have only uses 4 colors.
Someone out there versed in ML should write a speedy version of this program!
I hate waiting a day or more just to get one graphics screen displayed (I do it
a lot though!).
Bla bla bla...
Anyway, why don't you post your new modified program. I, even if noone else is,
am interested in seeing it.

1498. new software?

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-11 23:18:18 UTC
From: wilmott@topaz.rutgers.edu
Message-ID: <Oct.11.19.18.03.1988.6049@topaz.rutgers.edu>
Source record: 116652

It just occurs to me that it's been quite a few months since I've bought any new software for my trusty old 800xl. Not because I'm not interested in doing so, but because I just haven't heard of anything "new and exciting" software-wise in a while. So I call on any of you out there with any info about recent (last 6 months or so) software that you'd recommend, to pass that recommendation along this way...

Also, while on this topic, a few questions :

Which of the old major 8-bit software companies are still producing new software for us at the moment? (ie- Datasoft, Infocom, Microprose, SSI, Epyx, etc). I've heard rumor that Infocom has now dropped us... is it true?

Has anybody here actually seen this GEOS desktop DOS I've been hearing about lately? Is it really as good as what I've been hearing? (and who sells it and for how much?)

And finally...my favorite Atari 8-bit game is Alternate Reality. I've been hooked on it for 2 1/2 years now (first the City, more recently the Dungeon). I know the next installment isn't out yet - that's one thing I *know* I would have heard about if it was. Anybody hear anything about when it's *due* to be released, or if Datasoft even *is* still planning to continue the series???

Much thanks in advance...

Message-ID: <148@dalcsug.UUCP>
Source record: 116653

I have seen a newer ARC and UNARC utility. The ARChiver isn't available yet except as a Beta test version. Will advise as soon as I can. The UNARC program which goes with is apparently will do both ALF and ARC files and FAST. I haven't used it yet. But will advise as soon as I can. There is also a GIF Viewer program which is in ALF format as well as some Daisy Dot programs in ALF format. Both of these are around 20K UUEncoded. Enough responses will get a posting. I have found that about HALF of the requests that I had for the ALF utilities got bounced back to me so, I will entertain Mail requests, but NO guarantees. I will try.

The file names are :

SUPERARC.ARC - This is a Beta Copy so I can't send around.
UNARC.ARC - This is the Unarchiver
BAILEY.ALF - Daisy Dot Fonts
GIFVIEW.ALF - Graphics Interchanger Format Viewing program.

Well, looks like the annual run of terminal program questions has started.
I was asking all these sort of questions last year about this time.
But I eventually survived and found a workable configuration, so I figured
I'd let everybody know what I'm using.

I'm running Kermit-65, SmartT, and DOS 2.5 on an unmodified 130XE and a
SMM301 (I think) modem. (It's the one that came out about the same time
as the XE line, if I remember rightly, before the latest one. Tiny gray
box, direct Atari connect, 300 baud.)
I haven't had any problems in simply running that particular combination
(i.e., no apparent memory conflicts), but a few interesting things turned
up (none of which I'm complaining too loudly about -- it's a great way
to do VT100 emulation on an Atari!):
(1) There is an immediately fatal memory conflict with the keypad driver.
I have the source code to it, so I could recompile it if only I had the
time to sit down and look at everything.
(2) The reason I mention the keypad driver is because I'm not exactly
thrilled with Kermit-65's key bindings. But it DOES have keypad
mode, i.e., all VT100 keypad keys are emulated.
(3) If you hit the BREAK key accidentally, the system locks up. This
can sometimes be fixed by pounding on OPTION and/or ENTER. I don't
know if there's an exact sequence; I just mess with it each time
it happens. John Dunning (the author of Kermit-65) says he's
aware of this.
(4) Occasionally the system locks up unrecoverably after an hour or
two of use. This doesn't happen consistently and I'm not blaming
it on any of the programs I'm running. It very well could be my
hardware. I'm only mentioning it here in the remote possibility
that it's the software.

Now, the part that I'm sure you've all been waiting for after reading the
subject line: the Atari 8-bit Program Archives!

First, I don't have any idea if the archives are available somewhere on
the Internet for FTP. If they are, then this message concerns only Bitnet
users and the rest of you can skip it.

There is an attempt being made to put the program archives from this
mailing list/newsgroup/whatever on a server on Bitnet. Here they would
be available to any Bitnet site, or for that matter to any Internet
site, by merely sending a message by Mail or interactive facilities.
No TCP/IP required :-) [Flame for the day: RSCS s*cks.]

However, there is a definite impediment to rapid progress in the fact that
the only site willing to let us use their machine and the only person willing
to take care of maintaining the archives are a considerable number of nodes

away. For those of you on the Internet, this means that the travel time of a message or file can be rather long if the network is congested, and that there's a high probability of short-term system failure somewhere on the path.

Nevertheless, the program archives WILL be available on Bitnet! Hopefully, most of them will be in place before the end of this year. Right now things are still in a sort of testing (read: maintainer getting used to the weird IBM system) stage. Programs should start appearing on the server in about a week. I'll notify everyone when it would be worthwhile to grab a copy of the filelist. UUDECODE.LST will be the first thing up, of course :-)

For those of you who know about such things, the address is LISTSERV@TCSVM and the filelist is ATARI8-F. For those of you who don't know about such things, I'll explain later when it's actually worthwhile to get the filelist.

Jim

Neither have I. But then, I haven't been following the software scene as rigorously as I used to (for Ataris of any kind). I've just been too busy.

> So I call
>on any of you out there with any info about recent (last 6 months

I got FOOD FIGHT last month, and it's great. B-)

>I heard rumor that Infocom has now dropped us...
>is it true?

Infocom hasn't "officially" dropped Atari ST/XE support, but they have a new policy of "only the _really good_ [their words] material will be translated". Eg, unless they can guarantee it'll go over big, ferget it.

>Has anybody here actually seen this GEOS desktop DOS I've been hearing
>about lately? Is it really as good as what I've been hearing? (and who
>sells it and for how much?)

I saw it at the Glendale Atari Faire, and posted about it here about a month ago. It does look like the ST desktop, and the author claims complete compatability (eg, can run from the desktop) almost all Atari software. It sits in a piggyback (aka ICD) ROM cartridge, and takes up only 4K RAM. It should have started shipping at the first of October.

And by the way, it's the "GOE" (Graphics Operating Enviroment).

1502. 8-bit Program archives

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-12 21:35:00 UTC
From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM
Message-ID: <19881012213543.1.JRD@MOA.SCRC.Symbolics.COM>
Source record: 116506

Since Jim Shaffer's announced that his end of things is almost ready to go, I might as well announce mine.

The Internet version of the Atari 8-bit program archives is ready to go. It lives in Score.Stanford.EDU:PS:<INFO-ATARI.8-BIT>, and can be accessed via anonymous FTP. There's a file called -READ-.-ME-; please read it first for hints about what's where and how to use it.

As things get more organized, I'll be coordinating with Jim to make sure that everything's available in both archives.

Enjoy!

1503. Re: Mandelbrot

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-13 01:06:24 UTC
From: Thufir@cup.portal.com
Message-ID: <10002@cup.portal.com>
Source record: 116507

Believe it or not, I considered doing an action conversion of the simple Mandlebrot program that got posted to the net. I tried out Analog's program, but gave up after the first 10 minutes and first few lines. If the newer version of the program is posted and many people request that I do do a conversion, I might very well do so, providing that I have the time.

1504. ZMAG, ST Report, Vote

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-13 02:49:51 UTC
From: gdtltr@vax1.acs.udel.EDU
Message-ID: <2085@udccvax1.acs.udel.EDU>
Source record: 116508
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

Well, I have had a good bit of feedback on my vote request. While most replies said that they wanted them posted to the net, many didn't want them posted, some preferred mail, and very few were actually opposed to getting them through the mail. This and the fact that my posting of the mags to the net take up a full 2% of net activity (I made the top 20 :-]) led me to decide to try mailing them. I have never tried a mass mailing of this magnitude, so I would appreciate any tips (I am using a Vax running BSD 4.3). If you would like to be added to the mailing list, send me mail with a good return path and (ZMAG/ST Rep/both). If you have send me a vote, you don't need to send another request. If this doesn't work out, I may have to go back to a net posting. I hope this is a satisfactory solution for everyone.

Gary Duzan
Time Lord
Third Regeneration
Atari Enthusiast Extreme

p.s. I should be getting the new issues any time now, so get the requests in.

Ray Wilmott asks:

>Has anybody here actually seen this GEOS desktop DOS I've been hearing
>about lately? Is it really as good as what I've been hearing? (and who
>sells it and for how much?)

The Graphics Operating System, from Total Control Systems is *BETTER* than
anything you've heard about it...! Our user group was treated to a demo
of GOE this week, courtesy of programmer David Sullivan and the Michigan
Atari Magazine (MAM).

The version we showed was a disk based demo version of the finished system,
which will be released as a "double ended" cartridge. (You can plug another
cart in on top of GOE). According to David, he's received the cartridges
and GOE should be ready to ship very soon.

I'm an 8-bit user from Waaay back, but my old brown tank 800 hasn't gotten
much use since my shiny new ST came home... GOE could go a long way toward
revitalizing the 8-bit scene though, much as GEOS did for the Commodore-64..

When GOE boots, you are treated to a VERY close "workalike" to the ST desktop.
Your disk drives are represented as icons, and the ubiquitous Trash Can
is present for deleting files... at the top of the screen is a "Menu Bar"
virtually identical to the ST desktop's. Using the Keyboard, Joystick or
an ST Mouse, you can "double-click" on a disk icon, which opens up a
window and displays the disk directory.. in *either* text, or icons!

Running an .EXE or .COM program is as easy as double-clicking on it, and
you can copy files or disks by simply "dragging" them, just like on an
ST... deleting is as easy as dragging the file to the Trash Can...

The menus "drop down", and you can do many of the ST desktop functions
from them... the demo we saw even had "desk accessories" like a system
Control Panel and a Calculator!

The cartridge itself will allow 40, 64 or 80 column displays, and there will
soon be a "Developers' Kit" to allow GOE features to be used within your
own programs.

Other products in the GOE line will include a "Paint" program which will
reportedly allow up to 128 colors, and will be "NeoChrome-like", and an
80 column wordprocessor (David asked Atari to loan him an XEP-80 so he
could test his program on it, but they refused... XEP-80 owners will be
happy to know that his word processor *DOES* work with it though)

Future products include Desktop Publishing, Communications Terminals and
DataBase programs, all using the GOE window environment...

A few years ago, Commodore Business Machines revitalized the C-64 by packaging a copy of GEOS with every machine sold... apparently there had been talks with Atari to do the same kind of thing with GOE and the 8-bit Atari line, but Atari has apparently decided not to do it...

For more info on GOE, contact: Total Control Systems, 4156 Tolowa St., San Diego, CA 92119 (619) 270-0111 (Ask them about the special user group purchase plan!)

Disclaimer: I've got no connection with TCS, other than being an Atari 8-bit computer owner who's excited about this great new program..!

Major question: would they be accessible from UUCP? That's where *I* live and boy, I'd sure love to get at the archive!

Second point: even though this wonderful service may soon be available, I think I'll still post Kermit65 and handlers as originally intended.

Lastly, Jim, I'm glad to hear you're successfully using Kermit65 with SmartT handler! On your fourth point, however --

> 4) Occasionally the system locks up unrecoverably after an hour or

I've seen similar things happen, most notably on my own 800 before I moved up a bit to an 800XL... The 800 experienced a progressive worsening of performance under prolonged exposure to high (90+ degrees F) operating environmental temperatures. I know it was NOT software because even a VERY SHORT (1 sector) ML graphics demo I wrote, bunged up when run for several hours; therefore it had to be a hardware problem. However, the service place couldn't find any problem -- but they were air-conditioned and my apartment was at 100+ degrees most of the spring and summer, so that probably explains it.

Does anyone know an answer to these to questions?

1. Can a ST mouse be used through the joystick port on a 8bit? And be controled
by normal joystick comands or paddle comands?

2. Is there a way to binary load a file from basic using like an XIO comand?

3. Is there an XIO comand for the regular load and list comands?

Thank you for any help with these questions..You can E-mail
an answer or post it if you like....

1508. Downloading files from the net

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-13 15:16:17 UTC
From: rzimbins@umn-d-ub.D.UMN.EDU
Message-ID: <522@umn-d-ub.D.UMN.EDU>
Source record: 116512

This may be a question for experienced Net-ers to groan over, but I need to know the answer.

When a file is posted here, HOW DO I DOWNLOAD IT TO MY COMPUTER?
Obviously, an ASCII capture won't work because of phone noise, and I'm not aware of any transfer protocols here. Anything anyone can tell me would be helpful.

Bob Zimbinski

1509. Downloading with PCP

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-13 15:21:37 UTC
From: rzimbins@umn-d-ub.D.UMN.EDU
Message-ID: <523@umn-d-ub.D.UMN.EDU>
Source record: 116513

I've been having trouble successfully downloading 8-bit files since I began using PC Pursuit. It doesn't seem to matter what transfer protocol I use. 80-90% of the time, the transfer will apparently go just fine, but the program only half-loads then crashes, or doesn't work at all. Local DLs work just fine.

I'm using Amodem 7.5 and a 300bps modem.
Anyone know anything about this??

Bob Zimbinski

1510. Re: BASIC Atari 8-bit uudecoder

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-13 16:31:18 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8810131631.AA04776@mitre-bedford.ARPA>
Source record: 116514

Because of renewed interest in uudecoding, and because my attempt to reply to arrom@aplcen.apl.jhu.edu (Ken Arromdee (600.429)) failed, I have decided to post the uudecoder in Atari BASIC again. (Last posted earlier this year.) The program should be self-explanatory but documentation is available.

If you get tired of running BASIC to do UUDECODING, or you want to ENCODE something, I suggest you get John Dunning's assembly language encoder YAUE and matching decoder YAU (Yet Another Uudecoder). You can decode them using UUDECODE.BAS and then retire the BASIC version until someone else needs it to bootstrap themselves into using YAU/YAUE.

If you don't expect to do much UUDECODEing, UUDECODE.BAS by itself will give a good account of itself -- it appears to run at just about the same speed as Dunning's all-assembly-language version, a result that Dunning seems to concur with. Apparently all that sweat to avoid overhead in the BASIC calling program was well spent!

-John Sangster / jhs@mitre-bedford.arpa

1511. Need a cassette tape drive.

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-13 17:25:11 UTC
From: swillden@wsccs.UUCP
Message-ID: <736@wsccs.UUCP>
Source record: 116515
Cross-posted to: comp.sys.atari.8bit,misc.wanted

I need an interface for a cassette tape for an atari 800XL. I don't know if I need just an interface or an atari tape recorder too. I might be interested in getting a disk drive instead, if the price is low enough. I can probably build my own interface to a tape drive if it is not too incredibly complicated and if someone can tell me where to get a 13-pin male connector.

Could someone please point me in the right direction, or at least tell me what I need? If you're considering junking your old atari or have an extra interface lying around somewhere, I would be willing to pay for it. e-mail your responses to me.

swillden@wsccs

I can be hooked in, but I don't think it has a standard input format. In
other words, you would probably have to write your own handler to read it.

>2. Is there a way to binary load a file from basic using like an XIO comand?
>
In MyDOS and SparaDOS (these are the ones I know about) there is an XIO
command to binary load a file. Check your manual. As far as Atari DOS's, it
would be tricky. You would have to read the header data and do a block load.
You probably would have to write at least enough ML code to set up and exec
a CIO call.

>3. Is there an XIO comand for the regular load and list comands?
>
No, these are basic functions. You might try printing the command to the
screen and going into screen input mode (Poke 832,13;Poke 832,12 to return
to keyboard mode.) You will need to experiment with it for a bit to get it
to do what you want, so practice with a disposable program.

>>1. Can a ST mouse be used through the joystick port on a 8bit? And be controled
>> by normal joystick comands or paddle comands?

Some time ago, I posted a trak-ball handler which sits in page 6 and
is controlled by a timer interrupt. I was told that the ST mouse
works the same as the trak-ball, so my program might work. Maybe some
kind soul will re-post it from archives, as I have changed computers
and would have to re-type it in.

>>2. Is there a way to binary load a file from basic using like an XIO comand?

I have a simple assem routine appended to the trak-ball handler in
page 6. It is called by BASIC USR() commands, and just copies all the
parameters off the stack, sticks them into the right IOCB and calls
CIO. It passes status back to BASIC by putting it into memory
locations 212/213. This gives BASIC a lot more functionality, such as
copying binary data to&from disk without SLOW! single-byte PUTs and
GETs.

I just keep that page 6 stuff there all the time; I use the trak-ball
as a mouse. One button is not enough, though.

I read awhile ago in an ANTIC or ANALOG magazine an
article that explains how to hookup a Nintendo light
gun to the Atari system. I believe the article says
that the gun costs about $25.00.

This is of course for those who don't want to wait
for Atari to market their gun separately.

Yes the 8-bits can use the ST mouse. I don't know how you get the coordinates, but I used the mouse with the G.O.E. at the Atari Glendale Faire.

>2. Is there a way to binary load a file from basic using like an XIO comand?

It depends on the DOS. If the DOS is something like DOS 2.0 or DOS 2.5 (from Atari), I don't think there is any. If there is, I sure as heck don't know about it. (Then again, I don't go looking for valid XIO commands everyday.)

>3. Is there an XIO comand for the regular load and list comands?

I don't think so, because you can use those commands from within BASIC code.

The Atari ST mouse is identical to the Atari TRUE trackball
device. We realized this one day when we discovered we could
play missle command in true trackball mode (press CNTRL-T)
with the mouse. The votes were not in as to what worked better
but there was certainly some dissent as some preferred the mouse
for city defense.

I'm not sure, un the other hand, what pin the right hand
mouse button activates. Obviouly, it doesn't cause ay
trouble.

There is trouble with downloading on PCP to commercial networks (Compu$erve, DELPHI) as well. Apparantly PCP's packet switching does something funny when your packet sizes are larger than its. Timeouts occur freqently. I haven't heard of download being complete but incorrect unless you have a bad download program. I use 850 Express! (shareware) and I haven't had any XMODEM downloads which completed normally but wrere incorrect.

Scott McPheeters asks:
>1. Can a ST mouse be used through the joystick port on a 8bit? And be control
> by normal joystick comands or paddle comands?

The ST mouse *can* be used on an 8-bit Atari, but it requires the *TRAK-BALL*
handler... it can't be used with the normal Joystick or Paddle commands..

Darryl May of Atari Corp. had offered to upload it to GEnie... it may be
there now, but I can't say for sure...

Perhaps one of the Atari Corp. reps reading the Net can send the handler
over the net...

Just for fun, try using the ST mouse with the "Missile Command" cartridge,
after hitting CTRL T to enable the "hidden" TrakBall mode... it's a blast..!

MC is the only one I know of. The trakball almost works as a joystick
substitute when in joystick mode - it does quite well on the 2600 as well.
It's just that the software that reads it has to read it very frequently
so forget BASIC. Unless you use a joystick driver (should I post
mine again?)

I've just gotten off the phone with Total Control Systems and
I'm impressed with what the GOE is supposed to do. Follows is a
list of questions with the responses.

1) What is the required system configuration?
GOE needs 48k. The cartridge has 64k in it and few
things need to get loaded in.
2) is a DOS still needed?
Yes this does not take the place of DOS merely enhances
it. Also said it will work with most DOS. Specifically Atari dos
will work.

3) price now through end of october 50.00 after 79.95

A week or so ago, I was looking through the computer books in the library here at the U of D when I came across a book called "65816/65802 Assembly Language Programming". I imagined that the 65816 is what will be what is going to be used in the Turbo-816 so I checked it out. It does have a 6502 mode, but its native mode is about the same. In fact, as far I have determined, the 6502 mode does a couple setup things and then restricts the 16 bit opcodes from being used. The 65816 has a few ideas taken from the 65C02 (BRA, PHX,PHY,etc.), the ability to access 16Meg addresses, 8/16 bit selectable registers, and a movable stack (larger, too). I figure that there will not be much of a speed advantage unless the native 16-bit codes are used. Therefore, existing programs should run about the same speed except for calls to the OS (floating point should go a lot faster). What I would love to see is a SpartaDOS X-16 cartridge. Unix (or at least Minix) for the 8-bit would be nice too.

1530. More Mandelbrots!

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-19 13:59:47 UTC
From: slackey@bbn.com
Message-ID: <31017@bbn.COM>
Source record: 116534

OK, Atari fans! Here it is! New, improved Mandelbrot! No need to stand!

I think it's right.. just be on the lookout for typos.

Anyway, it has two new features, zooming and better accuracy.

When it is done drawing a screen, you will see a blinking spot in the upper left corner. You are looking at four corners of the select rectangle. Pressing the button and moving the stick causes the rectangle to change in size. Moving the stick alone will cause the rectangle to move without changing size. When you have the area you'd like to zoom in on in the rectangle, press any of the option, start, or select buttons and it will redraw the whole screen, scaling the selected region up to the full screen size.

In playing with this, I found that the approximation (quitting after 15 iterations) is too inaccurate when getting into serious zooming. So, I recoded it to go through the 15 [non-black] colors twice before giving up and drawing the pixel black. This will eventually fizzle out too, but hey give me a break. The only disadvantage of this is that in the full screen version, black takes twice as long to draw. I have a version that lets you select which algorithm to use by pressing a different button, but didn't feel like typing the whole thing in.

Oh - pressing the joystick button during the calculation causes it to immediately stop and let you zoom, before a full screen is done.

Impress your friends. -Stan

Source record: 116536

I've just gotten off the phone with Total Control Systems and
I'm impressed with what the GOE is supposed to do. Follows is a
list of questions with the responses.

1) What is the required system configuration?
GOE needs 48k. The cartridge has 64k in it and few
things need to get loaded in.
2) is a DOS still needed?
Yes this does not take the place of DOS merely enhances
it. Also said it will work with most DOS. Specifically Atari dos
will work.

3) price now through end of october 50.00 after 79.95

> is not too incredibly complicated and if someone can tell me where to
> get a 13-pin male connector.

1) You don't need an 'interface' if you obtain an Atari cassette drive - they are made to plug right into the SIO port, although they have only ONE SIO connector and therefore "terminate" any daisy chain. (This implies that you can't have the cassette unit and any OTHER terminating peripheral (the SX212 modem in SIO-direct mode, for example) connected at the same time.) There are two units in existence that I know of, the 410 and (someone correct me if I'm wrong) the 1010. The 410 is of the 400/800 generation, and the 1010 is of the XL generation, but EITHER should work with ANY 8-bit Atari. I personally have a 410 that I rarely use, but have just recently thought of an interesting use for cassette storage, so am loath to sell... sorry.

2) Disk drives are infinitely better: faster, random-access, more space. I HAVE heard, however, from a friend who got the new XM551 drive and does NOT like it... (Ooh, I can feel the flames already... ask 'aegnor@bsu-cs' about Mike W's experience; 'aegnor' is the one who was telling ME.)

3) I don't imagine the interface to a standard tape recorder should be too complicated; data is stored and retreived as audio tones on, I believe, the LEFT channel of a standard stereo recording, with capability to play right-channel audio through the TV/monitor speaker! You should be able to simply connect the audio inputs, outputs, and ground, to the appropriate SIO pins, as well as using some kind of control circuit (I do NOT recommend direct connection here) to turn the cassette player's MOTOR on and off in response to the appropriate SIO signals. (On the other hand, you could probably get away with leaving it ALWAYS on, in some if not all cases. There ARE cases where the computer NEEDS to start and stop the tape, however.)

4) Alas, I don't know where to get an SIO plug, but there must be SOMEPLACE since there is a continuing flow of SIO cables etc. Scavenge a cable if you have to. Probably the easiest way of obtaining one, when you get right down to it.

Hope this is helpful; good luck! If you DO hack together an interface to a standard cassette recorder, let me know; I have a reel-to-reel I'd like to try using...

Yes, the DataQue 816 is the 65816 chip and that chip is used in the Apple IIgs. It is an excellent chip and the developers package includes MAC/65 macros to allow use of the new commands.

Agreed about drives. I think tape recorders hate me (I, naturally enough,
reciprocate). There are a couple problems with the XF551, but nothing that
can't be overcome with a little hacking.

I think you will find it more complicated than you think. Remember that all
I/O devices attached to the SIO port MUST BE INTELLIGENT!!! I believe the
1050 drive has a microprocessor almost as powerful as the 6502 (not a great
statement, but it is better than nothing). An SIO call sends data to the
processor on the device and the device responds with the proper data, not just
some sounds. There is a pin on the SIO to allow an audio signal to pass though
the computer and out through your monitor speaker and a motor on/off pin, so
you could probably get it to play, but reading data off it is out of the
question without a processor chip.

If necessary, you could probably tap lines in an existing cable. I know

a couple people who built a voice synthesizer called Cheap Talk (it fits in a cassette tape box). The synthesizer was controlled through one of the joystick ports, but instead of hooking the output to an external speaker, he stole the audio in line from an existing SIO cable and send the output there, routing the sound through his monitor. If you want to look at the pinouts of the SIO interface, they are in Mapping the Atari XL/XE version p.198.

Alas, I have a bone to pick with you on this information, Gary. Are you sure you're not confusing the CASSETTE drive (and interface) with a DISK drive and interface? I don't quite see the connection between the original question of creating a cassette interface, and the microprocessor in the 1050 disk drive. The original posting had nothing to do with the 1050 or any other DISK drive; the poor fellow simply stated that he wanted to build an interface for CASSETTE.

Normally, you would be quite correct in stating that such a project would be complex because the resulting SIO device "MUST BE INTELLIGENT" -- but in the case of the cassette drive and interface, that is NOT so. To wit:

OS Listing, page 42 (line 1736, within the SIO Controller code):

"All devices EXCEPT CASSETTE are inteligent."

OS User's Manual, section 3, under "Program Recorder":

"The ATARTI 410 [TM] Program Recorder is a special peripheral. It uses the serial bus to send and receive data, but does not conform to the protocol of the other peripherals that use the serial bus."

That pretty well defeats the argument that the interface is complex in terms of its requiring INTELLIGENCE; however, you may still have a point, which I implicitly conceded in my first posting, that the data MAY or MAY NOT be transmitted back and forth as audio tones.

> An SIO call sends data to the
> processor on the device and the device responds with the proper data, not just
> some sounds.

I'm sure this is true, in most cases, but the CASSETTE as noted is treated differently. Section 11 of the OS User's Manual, under "SOUND GENERATION," refers obliquely to "... cassette FSK tone generation," and chapter II, section C, page II.26 (my God, I sound like a lawyer; forgive me!) of the Hardware Manual states that "Output data is normally transmitted as logic levels (+4V=true 0V=false). Data can also be transmitted as two tone information. ... In this mode audio channel 1 is transmitted in place of logic true, and audio channel 2 in place of logic zero."

Taken together, it sure SOUNDS (no pun intended) as though the cassette WRITE operation, at least, is performed in two-tone mode. Unfortunately, there is no corresponding informaition implying or stating ANYTHING about cassette READ operations.

> There is a pin on the SIO to allow an audio signal to pass though
> the computer and out through your monitor speaker and a motor on/off pin, so

> question without a processor chip.

Au contraire; it seems rather likely that he could get it to RECORD data, and that PLAYING BACK data is at worst still "up in the air." I'd say he still has a shot at it.

And if he succeeds and tells us how he did it, ya know what I'm gonna do? I'm gonna develop some really cool software here at home, at leisure, then save it to cassette as a casette-bootable binary, make a special adapter for my Walkman to connect to the Atari SIO port, take the whole shootin' match to the local department store's Atari XEGS display area, and quickly upload a sharp-looking showoff demo! They won't know where the heck it came from, unless I specifically tell 'em. Hehehe.

Yeah. In DOS 2.0 and 2.5, you can make a USR call to an undocumented address in the File Management System. I don't remember the address right now, but can mail (or post) the 1 line of Atari BASIC that is required. You can also do binary saves with a similar one line routine. Of course, it isn't very portable across different DOS's, so use it appropriately.

I will probably post the USR calls tommorow after I find it. (I still don't know where any of my software is after moving four months ago :-))

1541. Here Comes Kermit65 and the Means to Get It Working!

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-20 21:07:07 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <4421@bsu-cs.UUCP>
Source record: 116545

Hello, all!

Finally, the last obstacle to my posting Kermit65 has been removed; to wit, I verified that I *CAN* perform Kermit file-transfers while using the SX212 modem connected directly to SIO. (In fact, I'm using that configuration with Kermit65 to TYPE this!)

In the next few minutes I will queue for posting the following files:

- UUDECODE.BAS -- probably John Sangster's version; I think I saw it go by a few days ago, but will send it again "for completeness." ASCII capturable BASIC listing; capture it, and use the ENTER command to pull it in and execute it under Atari BASIC. It will let you UUDECODE the file which follows;

- YAU.UUE -- UUencoded YAU.COM (Yet Another UUdecoder) binary; you'll want/need this to uudecode what follows

- YAUE.UUE -- just for completeness; this is the Yet Another UUEncoder which lets you encode YOUR stuff for transmission.

- KERMITNR.UUE -- UUencoded binary of John Dunning's terrific Kermit65 program, with *NO* R: handler -- lets you "add in" whichever handler you need for your configuration, from those which follow. This was ported from the C64, and I just happen to have finally SEEN the original version for the first time; my professional (?) opinion is that John has IMPROVED on the original. Thanks John!

- KERMIT.UUE -- UUencoded binary of Kermit65 *WITH* the "standard" Atari R: handler, the one used with the Atari 850 Interface Module. Load-'n'-Go right from this file, if you have an 850 or compatible hardware.

- KERMITSX.UUE -- a homebrewed combination of KERMITNR.COM and the RVERT212.BIN R: handler that lets you use the SX212 modem connected directly to the SIO bus. Would not have posted this -- would have let you all "roll your own" from KERMIT.COM and RVERT212.BIN, below, 'cept we've had some awkward munging here lately and I want to make sure you get something that works. Oh yeah, this is UUencoded too.

- RVERT212.UUE -- UUencoded binary of the RVERT212.BIN R: handler that lets you use the SX212 modem as though it were the Atari 850 Interface Module. Seems to support all XIO operations allowed for the 850, either in actuality or with stubs. Included independently for those who'd like to use it in other contexts (should work with ANY software that looks for the R: device, providing said software doesn't overwrite RVERT212 with its OWN handler).

- SMARTT.UUE -- UUencoded binary of the "SMART T:" handler that lets your XM301 look like the standard R: device -- as far as I know! I may just possibly be mis-describing this, as I have never had occasion to use it myself.

- KERMIT.DOC -- ASCII text of the documentation for Kermit65 -- bet you almost thought I forgot it?! I almost DID...

Each of these postings-to-come will contain a brief description of the file contained, including the byte-count and checksum that you should get upon UUdecoding it.

I would like to request that if you know any of the following people, you make sure they know of these postings' appearance, as these individuals asked me to E-mail them everything, which I have NOT done in preference to just posting for everyone.

Keep your eyes open, and let me know if you miss a piece!

You can make an interface to connect a standard tape recorder to the Atari. However, you must first build a little circuit. The reason is that the Atari uses FSK modulation of the signal when it stores it on the tape, and you must add this FSK circuitry between the Atari and a standard tape recorder. Someone designed such a circuit and published it in the now defunct magazine Popular Electronics. I don't remember when it was published, but it was at least three years ago. If you can't find it, I will go through my back issues and find the issue for you.

Also, even though the SIO bus is intelligent, and the 1050 disk drive has a 6507 CPU, (which is a limited addressing, limited interrupts version of the 6502), the tape recorder is a dumb device. It uses the motor start stop to control the tape deck, and has no feedback as to whether the data was written properly. The ONLY time I ever use my tape recorder is when I get old software on tape, and I want to move it to disk. I then junk the tape, and put the tape drive back in the closet. (I used to play Pink Floyd tapes through the TV speaker before I had a stereo in the same room as the Atari, but that was 8+ years ago.)

Hope this helps.

1544. UUDECODE.BAS - posting 1 of 10 in Get Going With Kermit

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-20 21:54:38 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <4423@bsu-cs.UUCP>
Source record: 116548

The following is the straight ASCII "List" format program UUDECODE.BAS, which should be identical to that seen here a few days/weeks ago (depending on where you are). It is included here "for completeness."

Strip off all non-numbered lines before and after the listing, ASCII-capture it onto your Atari as an ATASCII text file, and ENTER it into Atari BASIC, where it will function as a UUdecoder sufficient to decode the UUencoded binaries which will follow. The UUencoded binaries should be ASCII-captured onto your Atari as ATASCII text files; then run UUDECODE.BAS on them to turn them into the original executable binaries. A binary-executable UUdecoder follows in the next posting, and should be the first (perhaps only) thing you need to use UUDECODE.BAS on.

----- CUT HERE AND ASCII-CAPTURE ---

In article <12418@eecae.UUCP> conklin@eecae.UUCP (Terry Conklin) writes:
>
>The Atari ST mouse is identical to the Atari TRUE trackball
>device. We realized this one day when we discovered we could

Hate to disagree with you, Terry, but it ain't so. I bought an Atari trackball for my ST. (Hate the little mouse. The buttons feel awful, and the plastic nubs on the bottom of the mouse scratch the hell out of tabletops...) In true trackball mode, without any modification, the trackball would only move the cursor in the -X and -Y directions. I.e., after rolling the ball every which way for a few turns, the cursor vanished somewhere in the upper left corner of the display.

Granted, it's a really simple mod to make it work perfectly on an ST. But it's not identical, right out of the box.

1546. KERMIT.DOC - #9 of 10 in Get Going With Kermit

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-20 22:52:58 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <4431@bsu-cs.UUCP>
Source record: 116550

Neither last nor least, here is the doc file for Kermit65. It should work exactly as described regardless of which version or handler you are using.

----CUT HERE AND PRINT----------

Kermit-65 Manual and bug list Page 1

Kermit-65 for Atari 800s

By John Dunning. Bug reports to me (JRD@Symbolics.COM) via Arpanet. Other net users will have to find some way of getting mail to Arpanet, then use the above address.

Kermit-65 is a port of the kermit-65 available for Commodore frobs. It runs on 48K Atari 800 family machines. Current version (second release) is 3.3.

Capabilities:

File transfer, text and binary:

Without going into excruciating detail here, Kermit-65 is a fairly complete implementation of a user side, using the KERMIT protocol. It's been tested against Kermit-11 under RSX, and C-Kermit under VMS and Un*x, and seems to work fine. For a description of what the KERMIT file protocol is all about, and something about how the it works, see the 'Kermit protocol' section at the end of this document.

Terminal emulation:

Glass tty, Vt52, or Vt100. Supports 3 flavors of screen configuration; Atari standard screen, 80-column pannable (40-column visible) like VTERM, and 80-column graphics, like V10SQR. Terminal emulation modes may be used in any combination with screen configurations, though some combinations won't work real well; for instance trying to do full-screen Vt100-style editting when using the Atari screen is a good way to lose.

Local file management:

Kermit-65 includes Directory, Erase, and Rename commands, allowing the user to do most kinds of maintainance operations without leaving the program. It also allows you set set the default drive to any value 1 thru 8, so you're not stuck using a single drive for everything.

Typing at Kermit-65:

The command processor accepts command lines, consisting of a keyword, optionally some more keywords, and optional values. Things in command lines are delimited by spaces, and terminated by <CR>. At any time, you may type '?' to get a list of valid completions for the word you're typing. You need not type keywords completely; however much uniquely identifies the word you want is enough. At any time, <ESC> will attempt to complete what you've

typed so far. Note that if you've typed a word, but haven't hit a <space> or <ESC> yet, so that the cursor's at the end of the word, '?' will tell you that there's only the one possibility. Hit a space, then '?', for a list of possibilities for the next word. Some commands are 'defaults' in the sense that if you type something non-unique, and hit escape, and one of the possibilities is a 'default', it will win over the other possibilities. One example of this is 'Send'.
Example: The following illustrates a typical interaction between you, the user, and Kermit-65. The stuff that Kermit types (prompts, echos of partial commands, and help) is on the left, stuff typed by the user is in the middle, and commentary is on the right.

Kermit types:	You type:	Comments:
"Kermit-65>"		Kermit prompts.
"s?"		User starts typing a command starting with "s", then hits "?" for help.
"Keyword, one of the following: Kermit prints possible set show for "s"... send Kermit-65>s"		and reprompts, with the partial command.
"et?"		User finishes the "set" command, and asks for help again.
"Keyword, one of the following: Kermit prints the (one) set possible completion. Kermit-65>set"		
" ?"		User hits a space, then asks for help again.
"Keyword, one of the following:" (various subcommands of 'set' here)		Kermit prints possible completions for words that can follow "set"

Kermit-65 commands:

Bye
Tells the kermit on the other side to log out, and exits Kermit-65.

Finish
Tells the kermit on the other side to exit server mode, but stay logged in.

Connect
Puts Kermit-65 in terminal mode, using whatever parameters are currently set for Terminal and Screen configuration. See 'Set Terminal' and 'Set screen' for more details.

Quit
Exit from Kermit-65 back to Atari DOS.

Exit
Same as Quit.

Get
<file spec>
Ask the kermit on the other side to send the named file, using whatever file and protocol parameters are currently in effect. See 'Set' for more details. Note that <file spec> may be wildcarded; assuming the serving kermit allows that. In that case the serving kermit may send several files; Kermit-65 will try to receive all of them.

Send
<file spec>
Send the named file to the kermit on the other side. If the file spec is wildcarded (using DOS FMS wildcard rules) all matching files are sent. In the latter case, the Kermit on the other side should be in Server mode, so that it can deal with a whole sequence of incoming files.

Receive
<file name>
Attempt to receive into the named file. Assumes the other kermit is already trying to send it. If no file name is given, Kermit-65 will attempt to get the name from the file-header information coming from the other side. This is the command to use after telling the other kermit "Send <something>".

Set
Baud

(50..9600)
Sets baud rate on the comm port to the supplied value.

Parity
Even, Odd, Mark, Space, None
Sets specified parity for the comm port. See the Atari 850 man for more details on the behaviour of the various parity options.

Word-size
Seven, Eight
Set frame size used for comm port. The default is eight-bit. The preferred value for this depends on what the parameters of the serial line are set to on the other side. In my experience, older systems will tend to use seven-bit configurations, more modern ones will tend to use eight-bits. If you're not sure, it usually works to use eight-bit.

Default-disk
<1..8>
Sets the default disk for all file operations. Legal values are 1 to 8, inclusive.

Rs232-registers
<16-bit hex number>
Directly sets some of the the values used when configuring the serial port. Specifically, the high byte is used as the AUX1 parameter for the XIO 38 (configure translation and parity) and the low byte is used as the AUX1 parameter for the XIO 36 (configure baud rate and word size). This allows settings to be used that aren't covered by the supplied keywords in Baud, Parity, and Word-size.

Debugging
Off, Terse, Verbose
Turns on/off various debug msgs strewn around in the code.

Eight-bit-quoting
On, Off
Turns on/off eight-bit mode quoting in the kermit protocol. The default is off.

File-warning
On, Off
When this mode is on, Kermit-65 will refuse to overwrite files when receiving. When it attempts to receive a file that's already present, it will alter the filename of the incoming file so as not to

overwrite the old version. The algorithm for altering the filename is to replace the extension field of the name with a 2 digit hex number, and retry. If the file still exists, the number is incremented. This repeats until a free name is found, or the extension reaches "FF", at which time the receive is aborted. (I think it's never possible to get that far anyway, as you can't put 256 files on one of these disks)

File-type
Atascii
This is a standard atari text file, and is the default mode. End of line is signalled by the ATEOL character ($9B). When sending, other ATASCII characters are translated to their ASCII equivalents, ie ATTAB ($7F) -> Tab ($09), ATRUB ($7E) -> Rubout ($7F). The file header info generated indicates that a text file is being sent. Receiving one does the opposite transformation.

Ascii
Files are sent/received as ordinary ascii-text. Line terminators are assumed to be CR ($0D) followed by LF ($0A), and are handled in the usual kermit fashion. No translation of data happens. This mode isn't the right thing for regular old text files, but is useful for sending around files that are output in plain ascii from various utilities. For example, I have a word processor program which produces formatted output files in ascii, intended to be dumped directly to a printer. This mode gets them over to my pdp-11's print spooler.

Binary
Data is sent in kermit binary form, no line terminators etc.

Flow-control
On, Off
Turns ^S^Q flow control on/off for the incoming line. See 'Com port handling', below, for more details.

Ibm-mode
On, Off
Turns on/off 'IBM mode'. This is apparently a standard thing in kermit implementations, made necessary by the wierditudes designed into the blue equipment. This code has been left as is, so it's got some chance of working, but has not been tested.

Local-echo
On, Off
Controls echo mode in terminal emulator. Default is off.

Send
End-of-line, Padding, Timeout, Pad-char, Quote-char, Eight-bit-quote, Packet-length
Sets one of the listed parameters for the transmitting side of the kermit protocol. Padding, timeout (seconds), and packet-length are in decimal, the others (character codes) are in hex. This command is primarily used when talking to a kermit that can't or won't use the standard set of protocol characters for beginning-of-frame, end-of-frame, etc. As such, it's not generally useful, at least I've never seen a kermit that required it. There are things that might come in handy, though. For instance, if you've got an exceptionally dirty phone connection, you might want to set the frame size down from the default of 94. In that case, you might say "Set Send Frame-size 30". Note that Send parameters can be reset by the other Kermit sending one of the kinds of packets that request certain values, so you may have to tell him directly, to get the effect you want.

Receive
All parameters settable same as 'Send'

Screen-driver
Atari
The standard 24x40 Atari screen driver. This mode does its output to the internal E: device. This isn't very useful for complicated things, but is supplied in case kermit's running someplace where there's not enough memory to do anything better. (Besides, I had to have all the code for it lying aound for other reasons, so why not?)

40-column
A 24x80 screen, using the character CTIA mode. Since that mode only allows 40 visible columns, the screen is pannable left to right, allowing any 40-column chunk to be displayed. The terminal code will attempt to keep the cursor visible by panning around while output is happening. You can also pan manually using the Start and Select keys. In this mode, reverse- video output works, but none of the other highlighting types.

80-column
A 24x80 screen, using the hi-res (320 bits/raster)
graphics CTIA mode. In this mode, both reverse video
and underlining are supported. This is the default
setting for screen mode.

Terminal-emulation
Vt100, Vt52, None
Sets the terminal emulation mode to the specified va-
lue. The default is Vt100.

Show
any of the same keywords as 'Set', or 'All'
Display the value(s) of the specified thing(s). 'All'
displays the values of everything in sight.

Status
Dump various goodies about the last file transfer; characters
in, out, naks, timeouts etc.

Directory [<filespec>]
Display a directory list from the default drive. <filespec>
is optional, if omitted, it defaults to "*.*".

Rename <from-filespec> <to-filespec>
Does a rename operation on files on the default drive. Either
filespec may be wildcarded, in which case the rename operation
happens according to the rules described in the ATARI OS FMS
documentation.

Erase <filespec>
Erases files on the default drive. Filespec may be wild-
carded, in which case the erase operation happens according to
the rules described in the ATARI OS FMS documentation.

Save
Dump Kermit-65 parameters such as screen settings, send/re-
ceive parameters, etc to an init file "KERMIT.INI" on the
default disk.

Restore
Read parameters from "KERMIT.INI" back into the running
Kermit-65.

Help
Gives a summary of the above command list.

Other interesting things about terminal modes:

Depending on what terminal you're using, there are several things
which may be of interest. In 40 or 80 column modes, there's a
status line under the 24 data lines. It displays what special
keys are active, and the status of the comm port. In 40 column

mode, Start pans the screen right, and Select pans left. In both
40 and 80 col modes, Option is used to get the kermit's attention.
In Atari mode, c-Y is used instead.
Once you have kermit's attention, it wants a character; one of:

C Break the connection
B Send a break (approx 1/4 sec)
S Display status

Function keys:

Kermit-65 can generate function key sequences ala VT100. The cur-
rent function key bindings are as follows: (c-sh- means
control-shift...)
c-sh-0..c-sh-9 keypad 0 thru 9
c-sh-. keypad dot
c-sh-backspace keypad minus
c-sh-, keypad comma
c-sh-return Enter
c-sh-q..c-sh-r PF1..PF4
c-sh-- Up arrow
c-sh-= Down arrow
c-sh-< Left arrow
c-sh-> Right arrow

Other key bindings for things not on the Atari keyboard:
sh-< { (left brace)
sh-> } (right brace)
sh-backspace ~ (tilde)
c-sh-backspace, or c-7 ` (backquote)

These key bindings aren't quite what I had in mind, but the OS rom
won't let me get at all the control-shift keypresses, so they'll
have to do for now. I encourage any feedback about how these
feel. I've been using them for a while now, and they don't seem
as bad as I expected. In particular, they work passably well when
using EDT (I'm typing this document with it), which I think is an
indication that they're useable, as it's a real keypad hog.

Other special keys:

The Atari key (/|\ on 800 vintage dinosaurs like mine, |/| on
newer 800XL vintage equipment) behaves in a special fashion when
using Kermit-65. It toggles a flag that causes input from the
comm port to be held up, rather than processed as soon as possi-
ble. This is useful for causing the screen to hold up temporarily
when in terminal mode. If flow control is enabled, it behaves in
the expected fashion; it'll tell the other side to shut up until
you press the Atari key again, to let pending input be processed
again.

The status line:

When in 40-column or 80-column terminal modes, there's a 25th line below the usual 24 lines of terminal screen. This is the status line. It will look something like this:

K65: Option + o v Rs ok

There are several interesting things displayed here: At the left side, after "K65", is a list of which special keys (option, select, start) are active at the moment. If you press Option, this will change to a prompt for the special characters that can follow Option. In column 22 ('+', above) will appear '+' or '-', or space. This indicator shows you the state of the flow-control logic; + means incoming traffic is enabled, - means it's disabled. Note that it when flow-control is turned on (see commands, above) this flag will toggle back and forth between + and - as the flow-control logic does its thing. If flow-control is turned off, it will just sit on + all the time. Column 24 ('o' above) will contain a blot if comm-port reading is suspended, space otherwise. In column 26, ('v') above, is the caps lock indicator. It will display an up-arrow if caps are locked, or a down-arrow if not. In column 32 is a message describing the last known state of the comm port.

Com port handling:

In its current configuration, Kermit-65 expects to talk thru an Atari 850. In principal, that ought not to be a restriction, but I (JRD) only have an 850 to test with, and don't know what requirements there are for other devices. I've tried to be scrupulous about sticking to the documented interfaces to things, however, so I'd expect any driver that adheres to the spec to work.

The port's opened and closed a lot; you'll hear it, as I've left the 'noisy bus' option turned on. It uses page 6 ($600) as an IO buffer. Since that's only 256 bytes, there's the possibility of overruns at high baud rates. When flow-control's on, Kermit will attempt to shut off the other side when it sees more than 50 bytes pending; it will turn it back on when there's less than 10.

As of this writing, Kermit-65 has been out in the field for a while, and seems to work ok with things other than 850s. One word of caution; I've gotten some feedback to the effect that the default timeout values I chose are too short for reliable operation at low baud rates. I've decided not to change the defaults, as you can easily change them in your KERMIT.INI file, and because most folks seem to have access to 1200 bps modems and things these days. However, if you're running at 300 bps and seeing reliability problems, try pushing the timeouts up to say 15 sec or so.

Other ramblings:

Version 3.3 loads at $2D20, and uses up thru about $B000. That means it'll only run on 48K machines. It appears to run fine on XL and XE equipment, but most of my testing has been on an 800, so there may be some problems. BTW, that load address was chosen because the latest version of DOS XL for Indus GT's uses up thru $2D14 when it's configured for two drives, and the 850 driver is loaded. Older versions of DOS XL take up less memory, as does DOS. I don't know what the requirements are for things like Spartados. If anyone comes up with a conflict, let me know, and I'll assemble you a version that's org'ed somewhere else.

On XLs and XEs, kermit-65 will require that the machine be booted with BASIC disabled, as it's not yet bright enough to detect that that's where it is and map out the cart. (if anyone knows how to do that, and feels like saving me some work...) Kermit-65 is available in 'bare' form, or with an autoloader for the 850 driver prepended to it. The bare version requires that you load whatever rs232 driver you're going to use first, then run kermit. The autoloader equipped version does that for you.

Kermit-65 Manual and bug list Page 11

For those of you who have YAU (posted separately) the byte count and checksum values for KERMIT.COM and KERMITNR.COM respectively are 24622, #x5F17; and 24408, #x1560.

Kermit-65 Manual and bug list Page 12

Credits

I blew it when distributing the first version of this document, and forgot to include this section. Mea culpa.

Many thanks to my beta testers, in particular Marshall Abrams, for his patience in dealing with initial versions of this thing, and for aid in making this document clearer. Thanks also to John Sangster for helping nail down my obscure terminal emulator bugs, and miscellaneous kibutzing. (Sorry John, I still haven't gotten in the key defining util. Maybe next version).

Kermit-65 Manual and bug list Page 13

Bugs and misfeatures:

There's no way to set the comm port to other than R1:. Does anyone care?

The help processor doesn't deal properly with upper-case, and thinks there are no completions.

Vt100 mode is missing still missing insert/delete character.

Blinking fields, bright fields, double-high, double-wide, and 132-col mode are not supported. (Reverse vid and underline are)

There's currently no way to set the screen colors.

It's possible to confuse yourself by hitting c-1 in terminal mode, as my screen drivers ignore it, but Atari's doesn't. You're fine until you break the connection, then everything appears to wedge up.

Flow control for the incoming side of the connection isn't implemented. This can cause problems when trying to send at high baud rates to a host that's got a stupid serial driver, or a small typeahead buffer.

The part of the command parser that deals with pathnames is completely bankrupt (that's what I get for using old code), and doesn't work properly unless it's told that a null pathname is legal. The result of all this is that when entering pathnames and asking for help before entering any data, it will tell you "input file spec or confirm with <cr>". Pay no attention to the man behind the curtain; you really do have to put a pathname in there for anything to happen.

Kermit-65 Manual and bug list Page 14

Bugs fixed for v 3.1

Save and Restore now actually do something, instead of being effectively no-ops.

Rename and Erase commands are now implemented. This means that virtually all file operations one cares about (while up/downloading) can be done without leaving Kermit.

File-warning mode has been fixed so that it really does something useful, instead of just bitching about the file conflict.

The pathname parsing substrate has been installed, so that defaulting and merging can be done in a reasonable fashion, instead of by ad hoc kludgery.

The screen hacking code has been cleaned up a good bit, so as not to be continually clearing the screen when doing transfers.

Logging code has been added to tell the user what files are being sent and received.

Status and help commands in terminal mode are now working.

The directory command now takes an optional filespec parameter.

Bugs fixed for v 3.2

Binary mode now works again. (Sheesh!)

Rename and Erase routines now make sure the comm port's closed before attempting to hack the disk.

The user interface has been cleaned up some; all numeric values other than character codes and some debugging info is now displayed and entered in decimal, rather than hex.

Bugs fixed for v 3.3

Fixed a dumb bug in terminal code that caused graphics mode to be entered at unexpected times.

Kermit-65 Manual and bug list Page 15

Fixed file reading code so as not to get confused and generate an extra byte when running under non-standard things like SpartaDos.

Cleaned up Directory code; using new pathname-mapping substrate.

Added support for wildcarded pathnames in Send code.

Fixed packet-dumping debug code to not mask off top bit of char, and quote everything to keep from interpreting screen hacking chars.

Fixed init code to look for an init file on D1, and read it if found.

Fixed flow control code so as not to wedge up unexpectedly.

Re-enabled the suspend-input capability, using the Atari (/|\) key.

Break (Option-B) in terminal mode has been fixed.

Cleaned up the font used in 80-col mode.

Removed Speedscript file type, as Speedscript apparently just uses plain vanilla text files. Changed default file type to Atascii.

Added caps lock functionality, similar to standard Atari kbd driver.

Fixed a bug in terminal mode that was trashing the stack.

Kermit-65 Manual and bug list Page 16

The Kermit Protocol

The following a brief description of the Kermit file protocol, excerpted from one of the many documents kicking around. If you already know what it is, or don't care, skip this section.

The Kermit protocol allows many (if not most) types of computer systems to effect, at minimum, error free file transfer with other systems and microcomputers over asynchronous lines.

Introduction

With the widespread use of personal computers the need for file exchange between systems has become of foremost concern among

users and managers alike. There are many commercial products available which meet this need, some of which may offer more advanced functions such as transparent record oriented file access. Networks that do this, such as DECnet, can be expensive, and if your computer or microcomputer is not on the network your needs won't be met. Transfer of files with removable disks can work, but generally only when the computers are of the same type, it's not very useful when the systems are removed in location. Rarely will a larger mini or supermini be able to read a microcomputer's disk.

A more realistic approach, from both cost and convenience, is to find a way to use ordinary telecommunications and/or in-house PBX systems to connect computers and microcomputers together. If a local connection using a PBX or front end switch is not available, there is always dialup access with standard 103/212 modems. Data can be transferred with very simple methods, such as TYPING a file on one system and capturing it on the other system, but this gives no protection from noise and overrun of data. It is not very user friendly either. What is really needed is a protocol to accomplish file transfer reliably and efficiently.

The first obvious use of any program or protocol designed to accomplish file transfer is to be able to provide the ability to support file uploads and downloads from minis and superminis such as the VAX and PDP-11 to remote personal computers, such as the Atari 800. It should also be widely available for many different micros and mainframes. File transfer from micro to micro, as well as from a larger central host, should be possible. The command interface should be easy to learn, and require no intervention from a central site operator or other user. The many implementations of Kermit follow these lines, and all versions allow some form of transfer in either direction. More advanced versions,

such as those found on the PDP-11, DEC10/20 and VAX, offer what is known as server operation, which allow the remote (connected) Kermit system to completely control the file exchanges from their system. Since as of this writing (October 9, 1985) there are available over 160 versions of Kermit available for numerous micro, mini and mainframe configurations, Kermit addresses this need quite well.

While the primary use of Kermit will likely be to support file transfer from microcomputer to mini/supermini and mainframe connections, there are many uses for Kermit for connections from mini to mini and so on.

The Kermit protocol

The Kermit protocol is designed to operate over normal asynchronous terminal lines. All data and commands are transferred with a packet oriented protocol, basically consisting of a start of packet character (normally SOH), followed by length, control, data and checksum fields. Communication is half duplex, in that for every packet sent, the sender must wait for either an acknowledgement packet (ACK) or a negative acknowledgement packet (NAK). Transmission is in ascii, with no requirements for the transmission of eight bit characters or control characters other than control-A for marking the start of a packet. All 'control' characters imbedded in the data are prefixed to convert them to printable characters, the same applying to eight bit characters if required by the characteristics of the line. Since there are many different implementations of Kermit, the protocol provides a mechanism by which the capabilities of two connected Kermits can be negotiated to allow for differences in the level of protocol support. Examples of protocol features that not all Kermits understand include data compression and transfer of file attributes.

The packet format is

```
+------+-----+-----+------+---------------+-------+
| MARK | LEN | SEQ | TYPE | DATA... | CHECK |
+------+-----+-----+------+---------------+-------+
```

where all fields consist of ASCII characters, and the char function converts a number in the range 0-94 (10) to a printable ASCII character by adding 32 (10). The MARK, LEN, SEQ and TYPE fields are one byte, the DATA field is variable in size, and the CHECK field is one to three bytes in size.
The MARK (normally control A) signifies the start of a packet. The length field tells how long the rest of the packet is. The SEQ field is used to insure synchronization used to detect lost or

duplicate packets. The SEQ number wraps around every 64 packets due to the need to encode it as a printable ascii character in the range 32 (10) to 126 (10). The TYPE field specifies whether the packet is a DATA or CONTROL packet. The DATA section is used for the actual transfer of data or informative messages from a Kermit server, this field can be up to 90 characters in length. Any character whose low seven bits fall in the range of 0 to 37 (8), ie, char and 177 (8) is less than 40 (8), will have the value 100 (8) exclusive or'ed (xor'ed) with itself and be prefixed by a shift character, '#'. Other shift characters may be use for eight bit characters if the line characteristics require such. Data compression may also occur in the data field, this is done with yet another shift code and byte count sequence. The CHECK field is a checksum, either a one character, two character or three character CRC check; the sender computes it and the receiver must compute it and compare. A checksum mismatch will result in the receiver sending a NAK packet (negative acknowledgment) which di-

rects the sender to resend the NAK'ed packet. The packet may be following by a terminator (likely an ascii 13). This terminator is NOT part of the protocol and is sent only to tell the receiver that a 'line' is present. Not all Kermit implementations require this; all Kermits will discard data outside of a packet in any event.

Error detection and recovery is by checksum, as noted, and by packet read timeouts. If the packet should be corrupted the checksum will be incorrect, the receiver will NAK the packet. If an expected packet never arrives within the timeout period, or if the received packet is not the expected one (as determined by the SEQ field) the packet will also be NAK'ed. There are limits as to how many times an expected packet will be NAK'ed without aborting the current operation.

Packet types

D Data
Y Acknowledgement (ACK), test may be in DATA field
N Negative Acknowledgement (NAK)
S Send initiate (Send-Init)
R Receive Initiate
B Break (EOT, end of transmission)
F File name header
Z End of file (EOF, end of current file)
E Error packet, text may be present in DATA field
G Generic SERVER command. The first character in the data field will be a command to a server, arguments may follow that character.
I Login, user and password follow in data field
C CWD, change working or default directory.

L Bye, Logout server
F Finish, Exit server, but do not log out
E Erase, delete files on server system
D Directory query
U Disk space usage query
T Type a file onto local kermit
R Rename file(s) on server system
K Copy file(s) on server system
W Who's logged in, as in sho sys, sy/s, dev tt
M Send a terminal message to a user
H Help, the server responds with commands it can do
Q Server status query
P Program, run a program
J Journal
V Variable, alter a Kermit setting

C Execute host command. The host command follows in
the data field.

Note that some of the generic server commands, as well as the C packet, may not be feasible for a given environment. For instance, the REMOTE LOGIN command, which sends the generic I command to the server, can only be done under systems that allow you to dial up and start a Kermit without logging in; the generic U command (disk space) is meaningless under some systems (like RSX) unless one wants the free space on the entire volume. No Kermit server will abort on receiving a packet it can't execute, it will simply send an error packet with an informative message saying it can't process the requested function.

An example of a Kermit-65 kermit telling a PRO Kermit-11 server to expect a file follows. The Kermit-65 command was "Send foo.txt"

(0)Atari sends: * S~# @-#Y(
(0)Pro sends: 0 Y~* @-#Y1~* ~T
(1)Atari sends: *!FFOO.TXTE
(1)Pro sends: #!Y?
(2)Atari sends: S"DThis is a test file#M#J
containing two lines.#M#JU
(2)Pro sends: #"Y@
(3)Atari sends: ##ZB
(3)Pro sends: ##YA
(4)Atari sends: #$B+
(4)Pro sends: #$YB

In packet zero, the Kermits exchanged information regarding their capabilities. The Atari sent an 'S' packet with the data for its

maximum packet length, default time out, number of pad characters to follow a packet (none, hence the space), use a null for padding, end of line terminator (a CR + 32), the prefix character for control characters, and a 'YES' to say the it can prefix eight bit characters with the default. It doesn't send any of the extension fields, like indicators for multi-byte CRCs, file header info etc. In packet 1, the Atari sends the filename the Pro should use for the file it creates. The Pro then sends the acknowledgement. In packet three, the Atari sends the first (and only for this file) packet of data. Note that the sequence #M#J is a carriage return/line feed sequence with 100 (8) xored into each character. The '#' character informs the other Kermit that it must xor the next character with 100 (8). In packet three the Atari sends an EOF packet, the Pro acks it. In packet four, the Atari sends a break packet which tell the Pro that no more files (of a possibly wildcard group) are coming and the Pro Kermit acks the break packet. The Pro kermit then enters the server idle state. More specific information regarding Kermit packets and state transitions can be found in the references listed at the end of the

article.

Future directions

With the advent of packet switched networks and satellite communications the Kermit protocol will likely be extended to increase efficiency over such links. The main problem is the half duplex nature of Kermit, the packet acknowledgements can take up to several seconds in transit thus drastically reducing the throughput. There are several possibilities under discussion and a standard should be appearing shortly.

Summary

With the knowledge that there are Kermit implementations for most personal computers in use it becomes apparent that the Kermit standard is well worth looking in to.

(End of protocol description)

For more documentation on what Kermit protocol is all about, see the extensive doc available from the Kermit folks at CU20B.ARPA.

1547. SMARTT.DOC - #10 of 10 in Get Going With Kermit

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-20 22:54:58 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <4432@bsu-cs.UUCP>
Source record: 116551

Some of the sharper-eyed of you may have noticed that I posted a list of 9 files, and have since been posting other files as "#xxx of 10" rather than "...of 9". Well, I forgot I had a doc file for the Smart T: handler posted just a few messages ago!

Here's the doc for that handler.

----CUT HERE and PRINT----------

SMARTT.COM - by Joe Hitchens July 86

(This version compiled at $2400, which seems to work with K65 Kermit/VT100 emulator)

SMARTT is a smart-modem emulating handler for the Atari 1030 modem.

Its commands may seem awkward, compared to the handlers for the Atari modems. But bear in mind it is pretending to be a hardware box outside your computer. If you have actually used a smart-modem these commands will be familiar.

Most programs expecting the 850 or similar device handlers should work with this handler. For serial I/O do close R: and reopen R: when finished like the 850.

The first time your program tries to open R:, you should see the SMARTT: prompt. At other times, it may be necessary to hit the "+" key 3 times quickly to raise the prompt. When at the SMARTT: prompt, the following Hayes smart-modem commands are accepted.

SMART T command summary:

atdt - pulse dial a number, for example ATDT7296046<return> dials and connects to NCAUG.

atdp - pulse dial, like atdt is tone dial.

ato - if you are at the SMARTT: prompt but you just want to go back online, get connected by saying ATO

atb - send a .5 second break signal

ata - put modem into Answer mode, to pick up the phone

ath - hang up the phone

atf - set full/half duplex toggle

That is the limited set of smartmodem commands supported by SMARTT. In practice, SMARTT does not seem to work with some programs. However, it does work with some R: telecom programs when R.BIN doesn't.

Sheet Feeder for Citizen MSP 15, 15E, or 25 For Sale

It's brand new in the box. I believe that it fits all of the above
models even though the box is labeled MSP15. I use an MSP10 so I
cannot use it myself. It's a long story.
I only need $75 (or a brand new sheet feeder for a MSP10).

I have kept out of this discussion basicly because I am lazy. I know I have
a circuit somewhere that shows how to make just such an interface. Lazy is
one reason but unnecessary in another reason. I have seen NEW Atari cassette
devices for about $25 and I'm sure you could pick up an used one for a lot
less. However, one company used to sell such an interface for about $40
(which is way too high even if you could find one) to use with a regular
tape recorder/player. I say don't bother, but a used Atari.

Priced to sell quickly!

Hi all! I have the following items I'd like to sell:
(all prices are in CDN dollars)

- 65XE (less than a year old) $100
- 800XL $100
- 1050 disk drive $150
- Epson Homewriter 10 printer (hardly used) $200
- Magnasonic 14" colour TV (less than a year old) $200

Atariwriter plus
MAC/65 cartridge
disk games
cartridge games

If you would like to have a PACKAGE DEAL, I will sell either keyboard, disk drive, printer, TV and Atariwriter for $500.

There have been some confusing ideas thrown about lately regarding cassette interfaces, so I would like to clear some of this up. (Of course, I don't know why anybody should believe my version over anybody else's!)

Atari cassette recorders are dumb. I have seen the inside of one myself, and there is almost nothing in them. Also I understand that the 1010 is no better than the 810, just repackaged.

Data is recorded serially (obviously), I believe at 600 baud. For recording the computer generates the tones (for two tone, of FSK recording mode), and the cassette drive simply records the audio signal. For playback the cassette drive converts the tone to a logic level, which is fed back to the computer. The circuit is primitive, nothing so fancy as a PLL. But you do need stuff beyond what a tape recorder will give you.

The early issues of Antic had a column just on stuff such as this. I would encourage to try to find some, they make interesting reading.

1556. AARGH! Keyboard problems!

Newsgroup: comp.sys.atari.8bit

From: jsf@psueclb.BITNET
Message-ID: <1300@PSUECLB>
Source record: 116460

The keyboard on my Atari 130 XE is shot. Took it apart to figure out why, and it turned out one of the little 'lines' on that plastic sheet inside the keyboard was broken (partially). Well we rubbed over it a few times with a big fat soft pencil and it worked! well, temporarily. After a while it stopped working again, so we tried various other remedies, none of which has helped any.

So the question is:

Where can I get one of those plastic sheets that goes inside the keyboard and looks like a pc board? Or, just as useful, where can I get a (cheap) keyboard that will fit in the case and is connector-compatible? The general deisgn of that keyboard is very flimsy, so i'd prefer a REAL type.

Please reply via e-mail if at all possible since I don't read this group regularly.

Thanks in advance,
John Faber

Oops... sorry about that... "macro fingers" hit "done" rather than "edit"..!

Just to add to the discussion of how the cassette drive (C:) works on the 8-bit Atari...

As Chris Chiesa indicated, the cassette device is a "special case", and does not operate as a normal SIO device. The POKEY chip translates the logic data into "two tone" audio (much like a modem does), then sends it to the cassette, which records it as regular audio. Reading data is the reverse process, with the audio "two tone" signal being translated back into logic data. Addressing the C: device with a LOAD "C:" or SAVE "C:" is what puts this method into action.

A normal audio cassette recorder *will* work, but not very well. The problem is that most audio recorders have too *good* a frequency response, and are designed to work with sine waves... the Atari data recorder has circuitry to clip the audio, square it off, and restrict the frequency response to the narrow range of tones coming from the computer. Thus, using a Walkman *may* work, but not as well as a 410/1010... I used to sell Atari software and experimented for a time with multiple recorder set-ups to do mass duplication, and the results were never very satisfactory with audio recorders... (but what the heck... give it a try..!)

In answer to the original request for information about obtaining an Atari cassette recorder, there is a company called B&C ComputerVisions which advertises in the Atari magazines, I see their ad in the November '88 ANTIC magazine. They used to list the cassette drive very cheaply, and may still have them. Other ads in the magazines may be worth calling too...

Now that I have spent the last four hours working on this, I feel that I should at least pass along some of what I encountered.

I need kermit... I need at GOOD TERMINAL PROGRAM that will emulate a smart terminal AND also go 2400 baud... and I know that is asking a lot for an atari.

Ok, I saved the uudecoder in basic and the binary one. Then I saved the kermitnr because I have a Rverter and that would be the appropriate one.

Next, I ran emacs on those files and removem the extra pre and post lines. Then, I trapped the text to my atari using express 850. WRONG! 850 doesn't get the DIAMONDS (the reverse single quote....) and so UUdeCODE.BAS went nuts. I found that error and called the system again... this time I did a XMODEM transfer of the edited files.... now the files had control-m control-j for EOLNs... and that is another problem... so I wrote a simple program to convert those controls into atascii 155.... then I entered UUdeCODE.BAS AGAIN.... to make sure I got the correct file... (ie: text trap vs. xmodem crc transfer) Ok, then I ran that on UUdeCODE.BIN. THAT CAME OUT... or so it appears. THEN I ran that on KERMITNR.UUC and it said that there was a BOGUS LINE.... an error. GREAT-- after hours of work. I tried running the UUdeCODE.BAS on KERMITNR.UUC to see if it was just the UUdeCODE.BIN (YAU.COM) that had the problem. GREAT! the basic program didn't report an error. I tried loading the KERMITNR.COM-- guess what? Yes, I got an error-- 136. I tried appending it to a handler to see if that would make any difference at all..... nope. I tried making it an autoload file because if there is an error 136 they usually load anyway. WRONG, it still gave me an error (this was all MYDOS) so I remembered that my vt100 terminal that I can't use anyway... only RUNS off of DOS 2.5 so I moved the file with the handler in front of it to a dos 2..5 disk. I booted it. At least the screen flashed BLACK before it went to DOS and gave me an error. I don't have an xl or an xe that works anymore so I couldn't try any of my special programs on it to look at it.

I am stuck with this piece of trash 800 and about 20 useless files that have something to do with KERMIT65.

CAN SOMEONE LEND A HELPING WORD or TWO???

1560. TURBO BASIC

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-22 11:45:26 UTC
From: alderaan@netmbx.UUCP
Message-ID: <1561@netmbx.UUCP>
Source record: 116464

Hi,

I would like to know if there in U.S. the TURBO BASIC interpreter is known.
TURBO BASIC is a very fast PD interpreter, a Compiler is also going away
with it. The author of this program (written in 1986) is Frank Ostrowski,
the same person who wrote GfA Basic !!!
If TURBO BASIC is known is the U.S., I wonder why nobody uses it (never seen a
TB-source here) ...

Our user group in Rochester NY also had a disk-based demo of GEOS recently.
Not bad! I was almost tempted to sign up for a version 1 copy. I believe
it will retail for $59.95 (onesies). The ROM cartidge saves most of your
existing RAM space. It uses the ST mouse or a joystick - we didn't see a
mouse demo'd, but it's got to be better than using a joystick. It's based
upon SpartaDOS (making use of files within folders/subdirectories support).

Didn't see the paint program or the text editor demo'd.

Message-ID: <2199@udccvax1.acs.udel.EDU>
Source record: 116466

Well, anyone can make a mistake. Since I don't own the operating system manual, I was unaware of the exception to the rule. My main sources of info at the moment are "Your Atari Computer" and "Mapping the Atari". Can anyone suggest any other good references and where to find them? We don't have much in the way of local vendor support (nearest Atari 8-bit dealer is some 40mi).
Thanx.

I was on Delphi last night and was going to join but got nothing but confused...I looked at all the menus and they didn't help my situation very much. This is what I would like to have help on..

1) I am going to be useing Tymnet .. Is there a monthly charge for using Tymnet even if I don't connect to Delphi every month?

2) Are there any other costs other than the 7.20 per hour during home time for downloading programs?

3) How do you get to the Atari SIG, I had 5 analog magazines in front of me and none of them helped.

Please E-mail or post if you can help..Thanks..

Source record: 116469

Bruce E. Shaver asks:
>I would like to purchase an Atari 800. Does anyone know of
>a place which is still selling these.

Try calling American Techna-Vision at 1-800-551-9995 or
B&C ComputerVisions at (408)-749-1003

Actually, you could use an upgraded Atari 400 (48K) to play MULE... it's
virtually identical to the 800, and can be obtained for about $50

In article <1561@netmbx.UUCP> alderaan@netmbx.UUCP (Thomas Cervera) writes:
>I would like to know if there in U.S. the TURBO BASIC interpreter is known.

I have used TURBO BASIC on and off for some time, mostly for its speed. I cannot use its added features, as I contribute stuff to mags, local user group, etc. and lots of them don't like the compatibility problems. If a feature is needed, such as fast binary I/O, I will add the little M/L routine it takes to implement it. Also, the way it handles I/O is slightly different in some cases, so I must always check anything I do to make sure it works in the other environment.

The last problem is that it won't work with SpartaDOS - both use RAM under the ROM. I use SpartaDOS because it is the only other OS I have that supports the XF551 DSDD mode, plus handles subdirectories.

As for the compiler - I have never been able to get anything to compile and run right, large program OR small. The last thing I tried was the Mandelbrot program I posted a little while ago. Sometimes I get an error message, such as DIM error, others just bad results and once the system hung. What gives?

There is a way to FIX your keyboard, but not well known. Keyboard problems come from little micro-hair trace cracks. The crack is essentially meaningless but is a gap, enough to cause trouble.

You can purchase special silver-based conductive paint. If you know where the crack is (which I thought you inferred) then clean it up with a little alcohol and PAINT it closed.

Beats nothing. And a new sheet of plastic breaks eventually too.

I heard that a bitnet fileserver was going up somewhere for the Atari 8-bit. Can someone tell me where it is? Are posting guidelines available? I'd like to contribute to the library, but I've never done anything like that before, so any help on this will be helpful and appreciated.

Also, my 130 XE keyboard went kaputz. I saw someone asking for help with it, and I would like to urge whoever answers the other guy to post it to the net so I can get some insight into my problem. Basically, the computer works fine, but all of the keys from 6 thru BREAK on the top row do not work at all. We suspect a torn run which should be easily fixed, but just haven't got around to it. Suprisingly, this is the third XE keyboard I've heard of with this problem, and I heard about all of them within two weeks of each other.

Well, that's my two cents worth. It's nice to post to the net again (after a rather lengthy absence), but then again, I never was a regular poster anyway.... Big deal, right? Right....

Hmmm... why "reverse-engineer" anything, when it is all thoroughly documented in the OS User's Manual? I know, I know, you DON'T HAVE the OS User's Manual... I was just pointing out that it should be possible. If the original poster doesn't "come through" for you on this, I am sure I could write something; I hacked a transfer the other way, from disk to bootable tape, all by my lonesome a couple years ago; even got it to work with multi-stage load files, after a fashion... could be considerably improved, but by the time I got the kludge version working, the need had passed...

> would really like to move my tapes onto disk! The tapes have games

Me too; would particularly like to see the Rubik's Cube thing, as I wrote my own version of THAT a few years ago, too (Binary is available if anyone wants to see it; source was lost).

There's also COMPUTE!'s Mapping The Atari, several editions in fact; and I have a set of OS listings from a couple of years ago so they were at least available at ONE time...

I've found that "Inside Atari DOS" is virtually impossible to find unless you can convince someone to part with their copy; I've been waiting a while now (Hi Brett) to receive a copy on that basis myself...

I really doubt it. Just as someone said in a previous note, the Atari uses FSK modulation to record on the tape. The computer modulates the signal when it sends it out, but the tape recorder de-modulates the signal before it sends back digital data to the computer.

However, if you want to build a converter for a normal cassette deck you can get the circuit out of the January 1984 issue of Computers and Electronics. (It was formerly called Popular Electronics. The magazine has since folded, so your best bet is to check with your local library.)

The article has a circuit based on the XR2211 FSK demodulator chip, ($2.95 from Jameco Electronics), and also a circuit to remodulate the signal and copy the tape on another tape deck. It also includes a short description of how it all works.

Good lock if you try building one, and let the Usenet community know how it works.

>
>I will probably post the USR calls tommorow after I find it. (I still don't
>know where any of my software is after moving four months ago :-))
>
Ok, so it took me a week to post the USR call. Also, my memory didn't serve me very well in my last posting. I don't have a binary save routine because the resident DUP routines insist on calling the full DUP package once they have saved the file. They DON'T execute a simple RTS. It would be possible to POKE an RTS in the appropriate spot before the USR call and POKE it back after the call, but it is really a hack. If you really need such a routine, I will post it, so ask if you need it.

However, here's the routine to binary load in Atari DOS 2.0 (I didn't try 2.5, but there is a good chance it will work.)

```
10 DIM A$(4):A$="hLH_":POKE 736,71:POKE 737,22:OPEN #1,4,0,"D:FILENAME.EXT":
X=USR(ADR(A$)):CLOSE #1
```

The characters shown above in A$ are only approximations. The real values are:

ASCII VALUE(HEX)	DESCRIPTION
68	lower case 'h'
4C	upper case 'L'
C8	inverse upper case 'H'
15	control 'U' (it looks like a fat underscore)

Hope this helps.
BTW, this will execute any init or run vectors, so if there is a run vector, it may not return to the BASIC program that loaded it.

Hi,
I seem to be having a bit of trouble using smartt with k65 (same old issue).
I downloaded them both off the net, uudecoding them on the unix system
and uploading them using xmodem binary.
The problem seems to originate with the smartt; to load it I need something
called a mem.sav. What happens is that after I load the k65 the smartt handler
seems to disappear, the symptoms being that k65 jams up when it goes into term
mode.
I tried appending k65 to smartt and making an autorun.sys out of them. BUt
what happens is that it starts to load (smartt header appears), but after a
while it goes into DOS.
My set-up is as following 800xl,xm301,1050...using DOS 2.5 on a 1050.

Thanx,
-Edi

1587. Hard drive woes

Help!

A friend and I have gotten a new 20 megabyte hard drive (half-height) for use with a bulletin-board system. We are using ICD's hard drive kit, and got everything assembled, partitioned, and formatted.

Problem is, no matter what we try, after a few days (maybe a week) of reading/writing to partiton #2, we end up getting "Device done" (directory scrambled) errors. It's not a physical error, since we can get the directory and files to be read if we try often enough. Still, it's a MAJOR inconvience, requiring lots of backup shuffling and code rewriting (development is a b*tch).

We're both 100% naive to the world of hard drives. Can anyone suggest a few reasons why this is happening? We've heard something about hard drive data "shifting" after lots of read/write operations; Is this it? Or is our case loose and the vibrations are causing problems? Or maybe the hard drive unit is not aligned properly?

We have NO IDEA what's going on. Plese help. (E-mail or post, as long as I can read and reply) THANKS.

--R.J.
B-)

P.S. We're using the new SpartaDOS X cartridge, if that helps.

1588. DataQue Turbo-816

Newsgroup: comp.sys.atari.8bit
Date: 1988-10-31 21:19:00 UTC
From: PARSONS@KSUVM.BITNET
Message-ID: <8811010302.AA03304@ucbvax.Berkeley.EDU>
Source record: 116492

This is a summary of the latest magazine report on the DataQue 816.
Most of it is sort of a re-hash of Zmag issue #124 (thanks Gary Duzan),
so I'll try to keep it to a minimum. BTW, this is reprinted without
permission (but surely I can claim exemption under educational use).
PS: My editing is in between the [brackets].

From Computer Shopper November 1988:

''The 'Turbo 816' by DataQue, for the Atari, will be available by mid November
for a suggested retail price of $99.95 (probably discounted by most vendors).
Included is a circuit board that replaces [the 6502 and OS chip]...
A debugger for 16-bit assembly language programmers will also be included,
and a complete Assembler may be offered either separately or with the pack-
age. On the new five-chip Turbo 816 board is a powerful 65C816 processor
that retains the 8-bit instruction set but has a ful 16-bit set as well...
The Turbo 816 [can address] a fully linear decoded address space of up to
16 megabytes.
...existing upgraded memory machines will be suported by the Turbo 816,
no matter which flavor or size...Users of the new CPU system will see an
immemdiate speed increase in all their existing 8-bit software. [To quote
one of the designers] 'just enough to tell there is something different.'
The OS chip has much faster I/O routines to all devices, making disk access,
screen writes, joystick response, almost everything faster. However, the
actual 'pace' of most software will be typically unchanged...math is all
being done with new routines that will dramatically surpass computation
times of the standard system...
But the real power of DataQue's device will be in the future applications
utilizing the 16 bit mode. Machine code will be 20 percent smaller and up
to 20 times faster than that written in the 'native mode' 6502. [Here's
a goodie] what is even better, disigner Ron Shue has arranged for memory
registers and stacks to 'hold up' under a mode-shift, enabling a programmer
to code half of his application in 8-bit mode, say to make use of existing
CIO/SIO disk access, then shift to 16 bit mode for computation and processing
-then back to 8 bit for more I/O-and on and on...
As for the new operating system, as I mentioned it retains the vectors,
flag, and entry points of the Atari OS, but is virtually 100 percent re-
written for optimized function with the new CPU. Included is a much
improved floating point package, a real resident R: device handler...and
room for lots of exciting things to come...[See Zmag issue #124 or back
issue #92 of Info-Atari8]
More about compatibility: Ron Shue [co-designer] has bent over backwards
to be certain that Spartados, Real-Time-Eight, MIO, and hard disk users
will have no ugly surprises after adding the Turbo 816. Only a tiny percent
of programs ([ones with illegal calls]) have had problems with the new
operating system. Chuck Steinman [co-designer] says that later upgrades

in the operating system chip will be offered to all users at virtually
postage costs, and Ron is expecting to offer a piggyback system software
control, for those who want to be able to shift between their old chip and
the new one [Omniview/Omnimon users].
[And last but not least, but the *most* interesting tid-bit] DataQue is
looking for qualified developers to be the first owners of Turbo 816, and
are looking for ways to add incentive for rapid application developement...
What does Atari Corp say about all this? [They have talked with Atari
through out developement fearing a blockade like the one involving the
ST 8-bit emulator. The article says that Atari has been 'generally
supportive and helpful ths for, although DataQue is still waiting for
written clearances on their operating system.' So they won't get sued
later. They had hoped to convince Atari to put the 816 in new XE's, but
Atari says 'Why would we want to redesign the 8-bit machine to be competitive
with our own ST anyway?' But Apple did it! (Sen. Bentsen: Atari you're
no Apple computer.)]

Source record: 116493

In the same article from the Computer Shopper was information on the pending graphic interface (yes, only one) for the 8-bit.

Some history: As far back as I can remember (a couple of months) there had been two separate graphic interfaces planned for the 8 bits. One was the 'STjr' (aka GOE?) by Merrill Ward and Associates and the other was Diamond OS by Alan Reeve of Reeve Software. Both of course, were to use an interface simalar to the ST/MAC etc.

The present: Merrill Ward has had trouble with the developer of Stjr, and has teamed up with Mr. Reeve to produce Diamond. Beta versions of Diamond OS were sent to DataQue, and run 'fine.' So only one graphic interface is going to be produced presently. Which, at least, will be a standard in a market with so many non-standard things.

The future: Is here. Diamond was supposed to start shipping in November I don't know if it will be the 1st or the 30th, but November is here!

The Diamond OS sells for $29.95. You can get additional 'modules' for use with Diamond. These 'modules' are Diamond Paint, Diamond Write, Diamond Publish, and the Diamond Programmer's Kit. All retail for $29.95 and require the Diamond OS cart to work.

For more information: Reeve Software

General ruminations on the new SDX cart from ICD:

Despite initial hestitation, I ordered it from ICD about a week ago, and received my cart about four days after the order was placed. Well-deserved praise goes to the shipping department for filling the order promptly (and correctly).

Remember all the lame excuses you used to offer before you didn't have to offer them? For example, before I got my first disk drive, I used to say "Why go to disk? The cassette is cheaper, albeit slower, but it still works." Then I finally went to a disk drive, and chucked that little 410. I said the same thing about two disk drives (eg = "Who needs two when one does the job just fine?"), but after I got my second drive, I changed my tune again. Same story with RAM expansion. And, you guessed it, the exact same thing has happened with SDX.

It is so nice to have all it all on ROM! Now I have greater control over my extra ram and my Indus. I've been using it for just a little while, but I'm sold. If you can afford it, you can't afford to be without it. It just isn't the same!

I'd be happy to answer what questions I can on SDX, but I'm not the real expert. I have seen a few names on GEnie that are also around here, and I'm sure somebody can come up with an answer....

"COMPETITIVE"?!?! give me a break! Since when would a somewhat faster 130XE be competitive with an ST? I feel Atari is being foolish for not helping this product along. This could give another boost to XE sales in new foriegn markets, where the C64 is king. One feasable possiblity would be to socket any parts that would have to be moved to install this upgrade, then give a discount if you buy the Dataque and the 8-bit at the same time.

Well, I've never been a big fan of SpartaDOS, but having used the X-cart for over two months now, it *seems* like a solid performer.

HOWEVER...I've been using SpartaDOS X those two months with a brand-new Seagate hard drive. And if anybody saw my earlier post, I'm having the most MYSTERIOUS problems with said drive (anybody care to re-read that post and tell me what is going on?). I'm not sure if SpartaDOS X is to blame for this, but...

Just a caevat, I suppose.

1596. SDX and Turbo

Newsgroup: comp.sys.atari.8bit
Date: 1988-11-01 22:46:31 UTC
From: AXDFM@ALASKA.BITNET
Message-ID: <8811012323.AA26430@ucbvax.Berkeley.EDU>
Source record: 116500

I have been asked by a couple of people if SDX does work with Turbo BASIC. The answer is yes. If you have an expanded memory machine (greater than 128K not including 128) then it works without any special handling. If you want optimum use of your extra banks or are using a stock 128K XE, then you will be forced to use a different configuration. This is done by creating a CONFIG.SYS file on D1: with the line USE BANKED in it. Others and/or the manual explain it better, but the bottom line is SDX and Turbo are a working combination....

The Atari 1010 program recorder (I have one) has two SIO connectors.

> I HAVE heard, however, from a friend who got the new XM551 drive and does NOT
> like it...

I have the Atari 1050 disk drive, and DO like it, although I wish it did "true"
double density, with twice the data storage of single-density, rather than
half again. And imagine what 512-byte sector support could do for program
interchange: "Sure, I can read that PC-DOS diskette!" (Happy Computers Inc,
are you listening?).

> right-channel audio through the TV/monitor speaker! You should be able
> to simply connect the audio inputs, outputs, and ground, to the appropriate
> SIO pins, as well as using some kind of control circuit (I do NOT recommend

As already pointed out, the Atari uses the Pokey two-tone mode to output FSK
on the serial output pin. (This FSK is, alas, apparently not phase-coherent,
which may be why we are limited to 600 bauds.) Thus, you can *record* Atari
tapes, with no further electronics, on a standard cassette deck.

To read them back, however, you must present the decoded data to the serial
input pin. That requires an FSK demodulator, the only "magic" in the Atari
program recorder. Before I bought my Atari 1010, I bought an Exar XR2211 FSK
Demodulator chip, and got excellent results writing and reading tapes. In
fact, the 1010 gave much *worse* performance than my simple one-chip solution!

One of these days, I'll do some serious experimenting with some custom tape
I/O software and the XR2206 (phase-coherent) FSK modulator. If a Bell 103
can do 300 baud in 1.5kHz bandwidth, 12kHz on a tape deck would give 4800bps
and using all four tracks in a stereo deck will yield 5 Megabytes on a C-90.

Hi there,

Well, I finally did it. I ordered a MIDI board for my 800XL this morning.
It is sold by Hybrid Arts, and it is comes with the MIDI board and Miditrack III
software. (For those of you with out 256K XL'x, or 130XE'x, you can only get
Miditrack II) The whole setup should arrive in about 4 days, and I will post
a review after I have played with it.

BTW, price is ~$185. I personally think that it is a bit steep, but I will
know more when I get it.

Just to update the information contained in Scott Parish's article about Graphics Interfaces for the Atari 8-bit systems...

My understanding is that David Sullivan, the designer of the "GOE" (Graphics Operating Environment) system, had some problems with Merril-Ward, the company which was to have distributed the system.

When negotiations fell apart, Merril-Ward (now re-named USA Media) contacted Reevesoft about distributing the Diamond graphics operating system.

BOTH new operating systems are alive and well. Diamond is indeed shipping, but only a disk version for the present, with a "demo" of the full cartridge system on the back of the disk. The Michigan Atari Magazine has Diamond now, and I'll probably be working with it soon, so I can review it...

MAM also has a pre-release version of the GOE cartridge, also on disk, which I've worked with, and the resemblance to my ST is uncanny..!

From other reports about Diamond, it seems, just on the basis of hearsay, as if Diamond may be the more powerful of the two systems, but as I said, I'll be checking them both out soon...

Film at 11...!

In my pre-atari, pre-sinclair days, I was fooling around with a
home-built 6800-based system. I built a simple mod-demod with a 555
(voltage controlled osc) and 556(?) phase locked loop. I connected a
UART to the 6800, and connected the serial I/O from the UART into my
widget. I used freq's like 3000Hz for a 1 and 3300 for a 0 or so. It
worked totally reliably at 1200 baud! I guess I should have tried it
at higher baud rates... I had fun anyway.

I agree with John - a Turbo-816 upgraded 130XE would not be very competitive with an ST. Not without a lot of s/w that would take advantage of the 16-bit mode. And even then, the 68000 would still prevail. (With the T-816, 8-bit progs. would see only enough speedup to make a perceptible difference, unless they do a lot of floating-point calculations. Chuck, if you are around, correct me if I'm wrong.) I was in the 8-bit conference on Delphi last night, and Matt Ratcliff pointed out that the T-816 has another problem: it requires h/w hacking. It takes special skill and/or tools to remove a chip from a 130XE board and install a socket - I know, I tried it myself and burned the board. (My 2nd XE went to a repair shop, where they had no problem socketing the OS ROM.) It would be nice if Atari would socket the 6502 and OS ROM, but I don't think they could be convinced to do this. Sockets cost extra, and they are extremely cost-conscious. Chips sometimes come loose from sockets.

But if my XE had the 6502 in a socket, I would seriously consider the T-816.

I had the same trouble with about the same system (I had an upgraded 400).
After trying every possible combination I could think of, I checked up on the
addresses of smartT: and k65. I don't have the addresses here, but I found
that SmartT: loaded after Dos, and K65 at $2300. SmartT: finished loading at
$22FE (now I remember). _However_, somewhere in transporting the file, some
bytes were appended to the SMartT: handler. On loading, DOS decided to
load these bytes too (despite the fact that the first 6 bytes of the file tell
DOS what to load where). This would be fine if SmartT: were prepended to K65,
but Kermit didn't like that (the mem.sav) problem. So, the solution I found
was to strip the bytes off of SmartT: which were appended, and then append
the new SmartT: to Kermitnr.com. I think this should work...

```
10 OPEN #1,4,0,"D:SMARTT.COM"
20 OPEN #2,8,0,"D:SMARTT2.COM"
30 FOR I=1 TO 1680: GET #1,A : PUT #2,A : NEXT I

```

Then, Go to DOS, append SMARTT2.COM to a copy of KERMITNR.COM, binary load the
result, and hope for the best. I don't have my system here to verify this, but
I'm 99% sure this will work. If there's any trouble with this, I'll check my
system in a couple of weeks when I get home. Good Luck.

1604. Flight Sim II <=> XF551 incompatible forever

Newsgroup: comp.sys.atari.8bit
Date: 1988-11-02 22:16:04 UTC
From: conklin@eecae.UUCP
Message-ID: <12907@eecae.UUCP>
Source record: 116408

In a previous posting, I mentioned that I had discovered the new XF551 was incompatible with the Flight Simulator II program's copy protection, and that I could no longer read FS II, which is exceptionally inconvienent since I am now in Flight School, but do almost everything in double density

There was a follow up message to the effect that SubLOGIC was aware of the problem and they had a fix disk.

As I have an exam tonight, I was again reminded that I would really like to put some of this stuff to practice, and remembered the posting. So I picked up my Flight Sim II box and called the number on the back, (217) 359-8482:

"Hello, I'd like to speak to customer service please"

"Well, perhaps I can help. What program do you have?"

"I have Flight Sim II for the Atari 8-bit"

"Thank you, I'll switch you to customer service"
...
"Hello, how can I help you?"

"I have Flight Sim II for the Atari 8-bit, but it wont work on my XF551 drive and I was told that you have an upgrade/fix for it"

"No, we do not support the Atari"

"Excuse me?"

"We do not support the Atari 8bit computers. If you have an 810 or 1050 it will work fine."

"Ok, was there a fix for the XF551 before you dropped 8-bit support?"

"No sir."

"What about the cartridge, will it read scenery disks?"

"If you purchase the game system, you can get the cartridge, but it will not read scenery disks."

"I see. Thank you very much."

Well f@%k me...

Terry Conklin, who, perhaps in the face of reality, still thinks his 8bit is
conklin@egr.msu.edu one of his most useful machines, regardless of the

^^^^^^^^^^^^^^^^^^

Yes, they have listened. If you format an IBM PC disk single sided, 9 sector
double density, you can convert files back and forth between the atari and the
IBM PC. Unfortunately, you cannot format IBM disks on the Atari since the
1050 ignores the sector hole, and the IBM doesn't.

BTW, on MS-DOS 3.x, to format a disk single sided with 9 sector tracks, type:
format /1 a:

It works quite nicely. I use it to move lots of software from usenet to
my atari. (Save the file to my workstation, walk over to the vectra, and FTP
the file to the vectra. Take disk home, and convert file to Atari disk. No
more fighting with Xmodem, Kermit and other stuff!)

I just went back over my Tech notes and early issues of ANTIC magazine, and it appears that Kenneth Sumrall is right... the 410 cassette recorder does contain FSK demodulating circuitry to decode the audio tones into logic level data streams... (must be the mists of time fogging my memory, but I thought I remembered being able to input data from a regular recorder... after thinking about it though, I think I *did* have to use the 410 to actually LOAD the cassettes back in... but I was able to record the output from the SIO port successfully (more or less) on a regular audio recorder, which was my goal anyway, in trying to mass-duplicate cassettes...)

What's even more interesting was a note I found in ANTIC, Volume 1, No. 1, which refers to a "Tape Operating System", which they abbreviate as "TOS"..

Now where have I heard those letters before...? :)

> In a previous posting, I mentioned that I had discovered the new XF551 was
> incompatible with the Flight Simulator II program's copy protection, and
> that I could no longer read FS II...

Well, first a bit about the FSII disk and cartridge. There IS a way to make the disk work with the XF551. But about the cartridge, SUBLogic is aware of the problem and they are fixing the cartridge version. I worked at Toys R Us this summer and talked to them extensively about it. The cartridge version comes with the new Atari game system and due to all the complaints, they ARE updating it.

Now about FSII and every other disk on the XF551 drive. My room got hit by lightning this summer and it fried all my old computer equipment. After a long hassle with the Insurance companey, I got my money and purchased my new equipment - among which was the new "top o' the line" XF551 Drive. As any other XF551 owner knows - all the stuff on the 1050 is not compatible if you notched and wrote on the back of your disk. (The XF551 writes on the back of the disk BACKWARDS - leave it to Atari to make unnecessary improvements.) But, there is a way to fix it. I subscribe to Antic Magazine (as EVERY Atari user should) and among the mail order ads, an ad caught my eye called the "XF551 ENHANCER." What it is is a chip with a switch on it that you must install on the inside of your XF551 drive and it makes everything compatible. It onlly costs $30 and it's well worth it (in fact, it's a MUST for every XF551 owner). The installation instructions are very good and I had no problems. So, look in a recent issue of Antic for the ad. If anyone wants, I will post the ad/address on this board (it's 2 A.M. right now and I don't have it handy.)

I have seen references to this several times now. Why does anybody care what
the back of a 1050 disk looks like? Is there a way on the 551 to access the
back of a 1050-formatted disk without turning it over? Under Atari DOS?
Please explain using no more than 2-syllable words.

Subject: need help seting-up kermit

It seems my previous posting was misunderstood. I guess it wasnt too clear.
Ill try to make ammends;
I recently got kermit65 and smartt off the net and tried to run them together
on my 800xl under dos 2.5. But it didnt work out. These are the results of my
experiments:

a) kermit65 without smartt loads and runs fine but the moment it goes to the R:
port it jams. This is expected because
without smartt there is no R: handler.
b) to load smartt I need a mem.sav . I am not really sure what that is. I guess
c) when I create a mem.sav lo, load smartt and then kermit it doesnt work.
d) when I prepend smartt to kermit and turn it into an autorun.sys, it boots loa
loads and then goes into dos. In such not working at all.

COuld someone who has a similar set-up (800xl,dos2.5,xm301) and has get kermit
running please contact me. Or anyone whohas encountered a similar problem do the
same.

I am not sure what it is that I am doing wrong.

BTW I am running the correct version of kermit (kermitnr.com).

Thanx
-Edi

1614. SpartaDOS X bug found

Newsgroup: comp.sys.atari.8bit
Date: 1988-11-04 16:06:39 UTC
From: rjung@sal13.usc.edu
Message-ID: <1834@nunki.usc.edu>
Source record: 116418

Since SpartaDOS X is one of the newer (and more exciting) products to come out for the Atari 8-bit in a while, I feel this warning is appropriate:

Some background: My friend and I have gotten a new 20 megabyte hard drive. We plan to use it in a new (rewritten) bulletin-board system. Since DOS 2.0 and most compatables were not made to handle heavy storage, we decided to switch to SpartaDOS 3.2. Fine and danday, lots of late-night weekend programming sessions.

SpartaDOS X: We went to the Glendale Atari Faire v.3, saw the new ICD SpartaDOS X cartridge, and bought it. We went bananas over the extra RAM, the increased directory capabilities, the built-in ARC, and other fun stuff. We switched from SpartaDOS 3.2 to SpartaDOS X with no efforts.

The bug: After a week of using the hard drive with SpartaDOS X, read/write errors would be generated. Any attempts to read or write would generate a "Device done" error, and the only way to get anything done was to rebuild the directory of the partition and drag out the backups. Needless to say, weekly (or even daily -- It appears to be based on the number of disk operations) backups is not a lot of fun.

The solution: After a few cross-country phone calls, the hard drive distributor suggested switching back to SpartaDOS 3.2. "If the hardware was at fault, you wouldn't have been able to format/partition in the first place". So, we went back to SpartaDOS 3.2, moved the backups over, and -- surprise! Everything works (at least, so far -- I'll check the system tonight).

Sorry for the long details, but the message seems to be clear:
*** SPARTADOS X can and WILL cause problems with hard drives ***

Now the questions are:

1. Does ICD know about this? The product is excellent in every other way, but this is a _really_ nasty bug...

2. Is this bug only in the "prelimiary" versions? If so, then why did me and my pal, and every other SpartaDOS X owner on the .net, pay money for the product?

3. Does ICD care?

OK, let's see if I can relay this through my experience. I bought the XF551.
It seemed like there was nothing major different about it. On the 1050, when
I filled disks, I formatted the front, notched a hole on the left side,
formatted the back, and then filled both sides of the disk with whatever.
Well, when I tried this with the XF551, it wouldn't work. It formatted the
front fine, everything seemed the same. But, when I notched the left side,
turned the disk over, and tried to format the back, it crashed. I'm not
sure how it all works, but when reading the ad for the XF551 Enhancer, it
said that the XF551 writes to the back of the disk BACKWARDS! So, apparently
while we don't really care what a 1050 formatted disk looks like, it does.
I just know that before I bought this chip I couldn't do everything I used to
be able to do with the 1050. Now that I have it, 98% of everything is back
to normal (I'd say it was a well-spent $30).

I got in on the Atari SIG conference on Delphi this past Tues, and Matt Ratcliff made a rare appearance there (he is on Delphi often, but not in the Conference). He said that he has tried out the disk version of Diamond you refer to, and that it wasn't all that great. Among other things, he mentioned that it took _40 swaps_ to do a disk copy. Also, it sounded like he had some reliability problems (I don't recall the details). He summarized by saying something like, "If the cartridge version isn't a whole lot better, I would give this a less-than-rave review." Also, it sounds like GOE is ready to go on cartridge, besides being more capable (again I can't recall more details).

Source record: 116422
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

I have decided to put off distribution of this week's mags until next
week due to the virus that has been shutting down systems. A week should
give most systems enough time to clear things up. I see no sense in sending
out the files and having half of them bounce back here. I will send both this
week and next week's files next week.
A few back issues are now available. If you made requests for back issues
more than 2-3 days ago, please resend them as soon as possible.
New members for the list are always welcome. Just send me a message with
the names of the mag(s) you want and a good path (preferably Internet) back
to you. Please keep the request as short as possible to avoid clutter on my
end. Thanx.

Sigh... I'm afraid I'd use up the entire Net bandwidth trying to explain this... I'll try to hit the "high" points, but for more "in-depth" info about the *supposed* XF-551 incompatibilities, watch for an article by Matt Ratcliff in an upcoming issue of (I think) ANALOG magazine.

First of all... THERE IS NO COMPATIBILITY PROBLEM..!

This is all a "semantics" problem, a massive misunderstanding of the way disk drives work...

The XF-551 is a *standard* Double Sided disk drive. It has a read/write head on BOTH sides of the disk, so it can write to both sides. A "single sided" drive, like the 1050 has a head on only ONE side, and it IS NOT supposed to write to the other side..! Atari owners have found ways to get around this by manually turning the disk over, and using the other side as if it was a *second* SINGLE SIDED disk... BUT... these "Flippy disks" ARE NOT "true" Double Sided disks.

Actually, it is the *1050* which "writes backwards" on the back side of a disk, because it is writing the back as if it was the "front" of another disk. When you put a "flippy" in an XF-551, the back side has been written in a *non-standard* way, and thus cannot be read, UNLESS you manually turn it over, just like on a 1050... in that case, it will read just fine..!

It's awfully hard to explain without some kind of illustrations to go along with the text... but the bottom line is, there is NOTHING wrong with the XF-551, it just can't read the back side of the NON-STANDARD "Flippy" disks without turning them over manually.

If you've been "flipping" your disks, you'll still have to flip them in an XF-551. Any disks you write as "true" Double Sided disks with an

XF-551 will not be able to be read by "flipping" them in a 1050...
these are not "bugs", it's just the way it works..!

BobR (Can you believe it..? I'm actually defending Atari! :)

I have the SDX and I have the config file set to:
USE WINDOWED
DEVICE SPARTA
DEVICE SIO
DEVICE ATARIDOS
DEVICE CLOCK

Everything works fine except the stupid thing keeps defaulting to OSRAM.
Does anyone know how to force it to use the WINDOWED ram?
My setup: 130xe, SDX, RT8, MIO 256K, XF551, Supra2400 modem

Ok, now for some more bugs....
1) Under my current setup SDX interferes with 2400 baud Captures. I use
DeTerm, and it normally works fine (under Sparta 3.2).
2) The X command only searches the current directory.
For example: X TEXTPRO
That command will disable the SDX and any Cart plugged into it, and then
attempt to load the file "TEXTPRO.COM" FROM the current directory. It should
search every directory listed in the PATH command and THEN search the current
directory.

Those are the only 2 bugs I know of so far...but I am collecting info on
others, so send me mail if you find any. Also, anyone who knows how to fix
that stupid WINDOWED problem, please send me the fix....

Thanx
Charles K Hughes

Well, the 551 IS a double sided drive. But, just as Atari did when they
made the new XL series (way back when) they made some improvements on those
that made some stuff not compatible from the old 400/800 series. When
I inserted a disk and formatted it in the usual way, I saw no difference
in disk space. So, I naturally just turned the disk over (like with the
old 1050) and tried to format it. It wouldn't even format. I went
through all kinds of routines and frustrations and just got down-right
ticked. Then I found out that they made some wierd changes. I bought
this chip and installed it and now it's all gret. Yes, the chip can
be disabled. There is a switch attached to it that you stick out the
back of your 551. One way makes it like the 1050 and the other way makes it
stay like it was made. I can vouch for this addition and still think it's
a necessity for any XF551 owner.

I've been told that the XF551 uses the same drive mechanism as the MS-DOS world does. These drives use the index hole in the disk when they format the disk. Therefore, it is not possible to flip a disk over and format the backside since the index hole isn't lined up with the sensor.

This is really no a problem however, since Spartados and others will let you format the disk as true double sided, double density and give you 360K on one disk. A much better alternative to flippy disks.

Also, I think the FSII incompatibility with the XF551 is not related to this problem. It has to do with the copy protection scheme that FSII uses. (Terry, am I right? Enquiring minds want to know :-) That's what happens when software is copy protected.

Details, details. Just look up the ad for Happy Computers in any issue of Antic magazine, (or look for ads from B&C computervisions or American Techna-vision, they also sell the Happy upgrades) What you want is the Happy enhancement. It cost me ~$100.00. Copies any disk, has full track buffering, hi speed SIO, True double density on a 1050, and also reads single sided MS-DOS disks on the 1050. A good investment for any Atari owner.

Installation is quite simple, just requires you pull two chips and put a board in one of the vacated sockets.

Nick DiMasi mentions that Matt Ratcliff reported in Conference on Delphi that he'd tried Diamond (one of the two imminent "GEM-lookalikes" for the Atari 8-bit systems), and found it somewhat lacking.

Tonight I had my first opportunity to work with Diamond somewhat briefly, and I too found some drawbacks. Just for contrast, we also booted up the "pre-release" version of GOE we have (*NOT* the "demo" version that had been circulated some time ago).

A full review of both systems will be forthcoming at a later date, but my initial impressions are that both systems have many strong points, and some weaknesses... I would *love* to see a GEM-like system that took the best of *both* Diamond *and* GOE...

>old 1050) and tried to format it. It wouldn't even format. ...

It seems that the 551 can read and write the back of a disk, but cannot FORMAT it.
I have done this.

OK, here's my theory, which is mine and mine alone:

I have read that the 551 uses the little hole near the center of the disk. Perhaps
it uses it, even in 1050 mode, when formatting. Note that when a disk is backwards,
the access holes in the sleeve are in a different place.

My theory continues:

The respectable? company that sells the tweek changes the formatting procedure to
use soft formatting instead of hard. They tell you that the drive turns backward;
if they told you that a paper punch would solve the problem, they wouldn't sell
very many widgets, would they!? I AM GOING TO TRY THIS TONIGHT!! And I bet half
the Atari net as well...

Stay tuned!

I tried to send this directly to charles@decuac.dec.com but the mailers
bounced it...

I wasn't trying to use MSDOS to write on the Atari disks. What I did was
to use a MSDOS copy program to copy an Atari disk onto a blank, unformatted
disk. This was a program whose normal function is to copy a copy-protected
MSDOS disk. Although sector size and the like certainly differ between
Atari and MSDOS disks, sector size, etc... on a copy-protected MSDOS disk
are also often different from a standard MSDOS disk; I was wondering if the
copy program would be able to copy the Atari disk, thinking it was actually
a copy-protected MSDOS disk and trying to copy the different size sectors
(and so forth) using the same routines it uses to copy the unusual layouts
of copy-protected MSDOS disks.

As I noted, I was partially successful. The MSDOS copy program managed to copy
some, but not all, of the Atari disk onto the blank disk. It copied enough that
some complete files on the (formerly blank) disk were readable and executable,
and I could do a directory of the disk and find that DOS XL thinks the disk
contains the same files that were on the original.

The PC's disks turn at 300 RPM vs. 288 RPM for the Atari. I have found it
impossible to write enhanced density disks on the PC without having the
last sector on a track overlap the first. The just isn't enough "room" to
fit all those 128 byte sectors.

I have no trouble reading and writing 256byte formats, e.g. PERCOM.

So do the Percom drives for Atari. I know that I'm not the only user
of those drives (why not? mine still work fine after 4 or 5 years, and
they are decent single-sided, single/double density drives.). In
fact, as I recall Percom (and possibly others) were the first to
_market_ double-density drives for the Atari 8-bit computers. (Atari
developed _but never marketed_ their double- density drive. It was a
dual drive, too. I wonder if it was any good?) Other makes of 8-bit
drives may or may not use the index hole when formatting; does anyone
know about Indus, Trak, Rana, Astra, ?

> Therefore, it is not possible to flip a disk over and format the backside
> since the index hole isn't lined up with the sensor.
>
This is what I've been told by Bob Retelle (who posted an excellent
article here about the '551), who has tried with Percoms, too. I
would have to get creative with a paper punch (or dig up one of those
Nibble Notch II gadgets, that punches a write-notch and index hole for
the 2nd side). I also found out (my ignorance is showing on this one)
that disks labelled "single sided" will usually work this way, i.e. they
are really double sided. Perhaps they are just not "certified" to work
on the 2nd side. (I usually find "single sided" disks are cheaper, but
then again I don't shop _everywhere_ for them.)

> This is really no a problem however, since Spartados and others will let you
> format the disk as true double sided, double density and give you 360K on

Yes, and you can still read and even write flippy disks by turning them over
as in any other 8-bit drive. (You just can't format them, without punching
a 2nd index hole, maybe a disadvantage to an 8-bit club librarian but not
most of us, since you can format it "true" double-sided.)
>

>

The 8-bit gurus on DELPHI (and I believe I saw this here too) said that the problem with FSII indeed stems from the protection scheme: sensitivity to disk speed is at least part of it. The '551 reportedly runs at about 300 rpm, instead of the usual 288 or so for other 8-bit drives. Does anyone have a _definitive_ answer to the question, "will Sublogic [ever] support the '551?" As far as other copy protection, ask me sometime what happened when I tried to boot the first copy of Synfile+ my wife and I bought (for use with the Illinois chapter of her professional association). That is, if you really want to know :-)

I have the program that was posted awhile back by Charles
Marslett (author of MyDOS) that does a fair job of reading/writing
Atari disks in a PC.

It claims to also be able to format Atari disks, but my experience
was that it left the drive in a strange mode, and I couldn't read a
PC formatted disk again until doing a reboot.

Note this will only read/write to Atari disks formatted in true
double density, although the source (asm and C sources included)
makes references to enhanced density. With a little work you
might be able to use it with single density disks.

It doesn't do as much as the happy, but then it's free. I'll
send a (uuencoded) copy to anyone that wants it (Email me).

I too have a percom drive, but alas mine is also capable of formatting
double sided disks. I have had it for about 5 years and have not had
any problems with it. On a similiar note, does anyone know if it is
possible to program the percom drive to handle enhanced format? If it
can handle ss/sd, ss/ds, ds/sd, ds/dd, then why not the enhanced density
used by the 1050? From what I understand the percom has a programable
drive controler.

I have done some cleanup on the format code (may still cause problems
on some machines, like my Premium/286 AT clone) -- and I am looking at
doing the single density I/O version. That will be much less portable,
so it may come in AT and XT version (or even brand name stuff like real
OSs, who says the IBM world is really standardized, . . . (:->).

%2. Is this bug only in the "prelimiary" versions? If so, then why did me and
% my pal, and every other SpartaDOS X owner on the .net, pay money for the
% product?
%
%3. Does ICD care?

A question or two for you - you called the hard drive distributor, fine. Did
you ever bother to call ICD? I've had good experiences with them in the past,
I'm sure they'd listen to you if you actually told them what kind of problems
you were encountering. You can get responses to questions particularly quickly
by calling their BBS. (Don't have the number handy, but both their voice line
and BBS numbers should be in the docs of every package you buy from them...)
It's awful hard for someone to fix a bug in a package when no one tells them
it exists. Maybe it's odd that they didn't discover it themselves before the
release, maybe it's only a bug in the version you have. You owe it to yourself
and to them to call up and find out, particularly since you seem to like so
much about it anyway...

I also have a Percom drive (the first SS/SD -AT88?) but it doesn't use the
index hole while formatting. I can notch the disk, put it in backwards and
format it fine. Guess that was before they worried about how to handle
DS disk drives.

> have tried it or might have the knowhow to perform this function.

I'm surprised that someone at ICD would tell you that since they have about
the only setup I know of that will work. HOWEVER, you are a long way price
wise from your goal. You need a hard disk of some kind (IBM type).
Then you have to buy ICD's MIO box ($239.95 for 256K model) and
their 8bit hard drive kit ($289.95 with MFM controller, $339.95 with RLL
controller). As you can see, you are talking about $530 without a hard
drive. Of course you have some side benefits. The MIO is a printer buffer,
256K RAMdisk, and has a built-in RS232 port for your modem. You could sell
your 850 interface and subtract that amount from the $530. :-)

There was another company that advertized briefly that had an interface
that was supposed to work. They had a funny name like Irata Verga or
something like that. I don't know if they are still in business.

It was a true double density disk I tried it with, and not an enhanced
density disk. And it still gave partial success...

And Kim Kimes writes:

>I'm surprised that someone at ICD would tell you that since they have about
>the only setup I know of that will work. HOWEVER, you are a long way price
[specifics of using hard disk with 8-bit deleted]

Unfortunately, a 1200XL has neither an XL-type Parallel Bus Interface,
nor an XE-type Enhanced Cartridge Interface. Therefore, it is probably the
ONLY 8-bit Atari that CANNOT support a hard disk. Even the venerable 400/800
series could use a rather awkward setup from Corvus and Dave Small.

>There was another company that advertized briefly that had an interface
>that was supposed to work. They had a funny name like Irata Verga or
>something like that. I don't know if they are still in business.

I believe the company name is Irata Verlag, and the only disk inter-
face I know of from them allows an XL/XE owner...except for a 1200XL owner...
to use standard FLOPPY disk drives. There is another company which manu-
factures a hard disk interface for the 8-bit line, but the name escapes me,
but its initials are BTL (e.g. BTL Hard Disk Interface).

Nick DiMasi writes, regarding formatting the "back" side of a disk by "flipping" it manually in an XF-551 drive:

>I would have to get creative with a paper punch (or dig up one of
>those Nibble Notch II gadgets, that punches a write-notch and
>index hole for the 2nd side).

Exactly right..! When I was helping a friend who owned a Percom drive, I eventually made up a small cardboard "jig" to help me mark the spot opposite the existing timing hole, so I could then *very carefully* insert the business end of a paper punch into the central hub hold of the disk jacket and punch the new timing hole (through both the top and bottom of the disk jacket... ONE SIDE AT A TIME...! You DON'T want to punch through the disk itself..!!) I finally ended up just taking his disks home and formatting them on my Atari 810 drive for him...

There used to be special "Flippy" disks available, with timing holes pre-punched on both sides... these would be ideal for anyone who seems to feel they still must "flip" their disks in an XF-551... they may be hard to find now though...

re: "if they told you that a paper punch would solve the problem, they wouldn't sell
very many widgets, would they!? I AM GOING TO TRY THIS TONIGHT!!"

My Percom SSDD drive (RFD-40) has the same characteristic: it takes more than a notch to enable formatting the back of a floppy. You have to punch an additional start-of-track sensor hole on both faces of the floppy jacket. To mark the position of the hole, I use a template consisting of another floppy, placed back-to-back with the floppy I want to "fix".

Also, I insert a bit of tissue inside the jacket through the hub hole to protect the floppy surface from being scratched by the hole punch.

> drive controler.

The Percom controller will work with any disk format with sector
sizes less than 256 bytes. Enhanced format will work, you just have to
reprogram the controller. PERCOM drives have 2 or 3 special SIO
commands that allow you to set the number of sectors per track, the
sector size and the encoding method (FM or MFM). The drives support
"any" number of sectors per track, limited only by how fast the drive is
spinning and sector sizes up to 1024 bytes, though only the first 256
bytes are actually readable.

I don't have an 8 bit or my doc's on 8 bit hardware anymore or
I'd post the commands that were used by PERCOM.

It's not mythical, but it's hard to get... At the last [11/5/88]
Suburban Chicago Atarians (SCAT) meeting, I asked an Atari dealer if
ICD had shipped him any SDX carts. He said that he has back-orders
dating from June! (And we're in the same state [IL] as ICD :-)

So, I gave up on asking for it for Christmas :-(

Message-ID: <8811151354.AA26329@ucbvax.Berkeley.EDU>
Source record: 116358

ICD is the only people shipping SDX right now. They are waiting until the final version is completed. Basically, the cart is done, but the manual is is being printed (the sign of true programmers -- docs ALWAYS finished WAYYY after the program!). So until all the components of SDX are complete, ICD is the only one shipping. They just want to give the hungry ones like us an oppurtunity to get our hands on it earlier than normal.

Until the final, all you get from ICD when you buy from them is a prelim manual and the cart. The policy is this: You'll get the final copy of the manual for free (they'll send it to post. paid IF YOU SEND IN YOUR REG. CARD!) and you also get the first ROM update at less than 1/2 price. This is an excellent way to get in on the ground floor without getting stuck with the buggy early versions.... I don't have ICD's address around here, but you should be able to find it on a BBS or in Antic/Analog....

BTW, the price (if you buy from them) is $79.95.

Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit,rec.games.video

Has anyone heard anything about Atari producing a 68000 based
home video game system? Rumors flew several weeks back, but
I've heard nothing new lately.

Specifically, if such a machine does/will exist, I was hoping to get
answers to these questions, before I settle on buying a Nintendo
or Sega:

* How does it compare to the Sega, Nintendo, and Atari XE systems
available now? What are the specs for these 3 machines,
and what are they for the new, rumored Atari box? Along these
lines, what kind of input devices (light gun, 3D specs, etc.)
will be available?

* When will it be released? (Rough guesses -- plus or minus
1/2 year -- are welcome).

* How about cost and projected game availability (within, say,
1 year of release)?

Post or e-mail replies. I'll summarize if the response warrants it.

If you want the SpartaDos X cart then call ICD themselves. Their number is (815)968-2228.
Currently they are shipping it with a preliminary manual which has a major bug in it. Wherever you see the word "WINDOWED" substitute the word "BANKED". That is the bug, took me days to figure out.

> ....
> Port'naybl @ The Three Gadgeteers

If you don't like the 810 (not 850) disk drive, why not just buy a new one. It's a h*** of a lot easier than building one, unless you are a h/w masochist. (Or so I gather, I don't hack on h/w.) The new XF551 Atari drive would be a good choice. Since you have an IBM / other computer background (it seems), you should understand "true" double-sided floppy drives. (Some of us Atarians have gotten so used to flipping floppies, we flipped out when we saw a drive that deals with the 2nd side of a non-flipped floppy! [Try saying that fast, over and over again :-]) But not me, I have Percoms, and I never got into punching 2nd-side index holes...

From: BIW109@URIMVS.BITNET
Message-ID: <8811180302.AA02242@ucbvax.Berkeley.EDU>
Source record: 116366

Actually, connecting a hard disk to a 1200xl should be possible
if you know a bit about hardware. 'All' you have to do is find all
of the signals that are present on the expansion bus of a 130xe,
and bring them out of the computer. the signals are all listed in
'Mapping the Atari (revised edition).' I'm not sure if all of the
signals are generated by the 1200xl, some may have to be derived, but
if I remember right, most of the extra lines you will need are
there (the high order address lines, I can't remember what else
they had). Even if this can be done (I don't have a schematic
of the 1200, so I can't say for sure) it will not be cheap..
Incidently, if anyone out there has a copy of a 1200xl schematic,
I would be interested in getting a copy. I would be willing to pay
for one..

This can be done with a single chip. There is a nifty little chip called the MAX232CPE which allows you to convert RS232 voltage levels to TTL levels with no extra power supply (i. e. with just the five volts available on the joyport). This can be hooked up to two of the PIA pins in the joyport, as well as the voltage lines. Only problem with this approach is that it may require a prohibitive amount of onboard software - I don't know how much the device handler which would have to be written would entail, or how much of the work which has to be done can be abstracted to the handler. It may be that you would also need to add shift-registers and an external clock, but these are all still non-proprietary chips.

Source record: 116371

I am looking for a copy of the TB runtime package. I used to have it, but due to a little stupidity, I really messed up the runtime loader. I have a couple of compiled programs (w/o source), that I would like to use, but just can't do it with Mr. Runtime. It isn't on the bitnet fileserver at tcsvm, so if someone could either put it there, or get it for me and mail it to me, I'd be really grateful. But don't worry about me, I'll be happy until I can get my hands on it.

I would also like FrOst BASIC (the 800 version of Turbo BASIC). That is much less of a priority, but it sure would be nice. Again, this one is in the Atari8 library, but not the bitnet fileserver. If someone would get them from the library and mail them to me, I'd be even more grateful!

For those of who you have an SIO direct-connect modem (ala XM-301 or SX-212) and a SIO-centronics parallel printer cable, you know that you can't use your printer and modem at the same time. It was always a real pain not being able to dump a screen to the printer while on-line, but it really got annoying everytime I wanted to print a listing or a text file (had to manually swap the cables around, etc).

I found a little thing in Best Electronics' latest catalog that got around all of that! It is Digital Device's "Ape Link" kit. It gives you up to three extra SIO ports on your Atari! If you buy it in kit form (instead of each individual part -- there is no fully assembled version), then you'll have a little soldering to do (not much). The procedure is simple and straight-forward. I've got it configured as three SIO ports, but I can easily add another SIO in, so I can use all three ports for SIO for perireprials ((as of now, one of the ports connects the Ape Link to the daisy chain).

The bottom line is this: It's easy and awesome. If you are in the same boat as I was, then I hearitly recommend it. Best Electronics was very helpful too. Good place to order from....

>
>Is it possible to partially format an atari disk or do you always have to
>format the entire disk?

As I understand it, the 1050 is intelligent only in the fact that it doesn't have to be completely run from the computer. The Atari sends a format command through the SIO port. Your DOS will then normally wait until the drive is finished with the physical format so that it can write the DOS info to the disk. You may have noticed that if you start formatting a disk and then hit the break key a few times, you would be returned to a DOS menu, but the drive would keep formatting. A drive would have to implement a "format track" command in addition to a "format disk" command to partially format a disk. I understand that this is one of the things that the Happy upgrade does. Other upgrades may do this, but I'm not sure. I don't think my US Doubler will do it.

>I have heard that the 1050 'is intelligent' ,can you program the 1050
>so you can write your own DOS?

It is not a matter of programming the drive, but the computer. Your DOS will have to patch into HATABS (I think that's the name), set MEMLO, trap RESETs to initialize it, and write the code. Machine Language is the only real way to go for writing a handler. A real C compiler might hack it, and Action! might barely do it, but ML is best. Inside Atari DOS gives you full ML source code for Atari Dos 2.0s and is a real help. Mapping the Atari is a necessity for any true Atari hacking.

>
>please,if somebody has an answer to these questions (perhaps a low level
>SIO call that i haven't discovered yet can do the job????) email me

I think $E459 is the address for the SIO call vector. Better check Mapping the Atari on this, but if you set up the device control block (DCB. Note that CIO/IOCB calls require a handler while SIO/DCB calls access the SIO port hardware directly [though I think you can patch in a pseudo-serial device {i.e. SpartaDOS UltraSpeed I/O. Note: I'm not too sure about this one} by rerouting the vector]) and do a "JSR E459" it will executed an SIO call independant of any handlers.

Well,
If you really want to interface another brand of disk drive to
your Atari 800, then it will take a lot of work. I worked on a project
where we built 3 custom computers to hang off the Atari serial bus,
but it was a big hassle. It would definately be less expensive
(esp. in the area of time) to buy one. However, if you really want
to do this, then get hold of a copy of Atari's Hardware Techinical
Reference Manual. It contains all the needed information about the
serial protocols, timing, and other such stuff. Good luck . . .
.

This is, indeed, a GREAT chip. All you need is the chip, 5V, and 4 common
electrolytic capacitors and you're ready to go. The chip "generates" the
~ +/- 12 volts for the EIA RS232 using a voltage doubler circuit on the
chip! The power drain seems pretty low too :-)

|>This can be hooked up to two of the PIA pins in the joyport, as well as the
|>voltage lines. Only problem with this approach is that it may require a
|>prohibitive amount of onboard software

There used to be a modem made by MPP which worked through the joystick
port. Someone out there in net.land may have this and can slip it under
the rug to both of the askers. Also around is something that I think
was called Rhandler which was a R: device driver that would drive the
joystick port modem (or 850 I think too!) using R: as a device name (so
you could use any terminal program). Check Compu$erve or a local Atari
hacker for the latter (I think it may be public domain).

Of course, the best part about the joystick port modem idea is the fact
that you can use the disk drive and RS232 ports simultaneously without
any special suspension/resumption on the disk or RS232 port's part.

Hope this helps!

If you wanted an all-software approach, you could use a "bit-banger", which is how I understand the ATR6000(?) box worked. To keep hardware prices down, they used its CPU to monitor the SIO line and determine what bits to load into bytes. They had a bit of work getting it to run at the 19200bps SIO port speed, but 300bps, and maybe 1200bps, should be doable by stealing some Pokey channels to use as a real-time clock. The interrupt code for the timer samples the TTL line for the receive data line (and sends a bit out on the transmit data line when appropriate), and every N (which must be more than 2X the incoming bit rate with this approach; I believe 3X can do it, but 4X is more reasonable) samples, makes a decision on what the incoming bit is. (Since there is no data clock which, I understand, intelligent devices on the SIO port use, your "software UART" needs to oversample in the same way that a real UART does in hardware, to find the start bit and properly track data transitions.)

But when I got my Atari Technical Reference Manual and learned that the two interrupt lines are unused, I got an idea for an even lower-overhead idea: Present the TTL Receive Data line to one interrupt pin and, using an inverter, its mirror image to the other interrupt pin. On each interrupt, you check the video processor's scan counter and the low-order part of the 3-byte system clock to determine how much time has elapsed; all the intervening N bit times have the same value (1 or 0). But with this scheme you still need a "watchdog" timer, probably a Pokey channel interrupt, which is set when each start bit is received, and tells you when the end of the byte is, since you can't rely on a transition just before the stop bit.

But perhaps the simplest solution would be to use the same technique the program recorder uses: turn on the motor control line, send data out without clock or attention signals (so the intelligent devices don't get excited), and use Pokey's own UART circuitry to decode the incoming async characters at whatever baud rate you specify. Of course, if you want the capability of writing the incoming data to disk, you need to XOFF the communications line, temporarily shut down your driver (turning off the motor control line, which keeps the SIO line transitions from going through the device and into the

modem - an AND gate may do the job here), and write to disk. When done, raise
the motor control line and send an XON.

Subject: PC files to Atari

The program has a bug in it; if you try to copy a file from an MS-DOS disk to an Atari disk, in binary mode (/B), you get problems; although the MSDOS file is opened in binary mode, the program forgets to turn off translation. Therefore your binary file on yourAtari disk has all its tabs converted to 0x7F's, etc.... Also, after I copy files (I used "util /b /w filename a:") I get the message Invalid path <<a:>>

Source record: 116381

I have an Atari 800 that has been sitting in
a closet at home for about 5 years now.

The problem is this: When I turn the unit on it behaves
normal for about a minute and then crashes spectacularly
with brightly colored moving text and graphics on the
screen and random noise. I suspect a loose connection
somewhere--- has anyone had this problem? How would
I go about getting the thing fixed? does atari still repair 800's?

any info would be greatly appreciated!

...

I think what we have determined is that the only function a 551 cannot do
is FORMAT the back of a standard disk, unless you do one of the following:

Get a special kind of disk whose sleeve has an extra hole so that the
timing hole can be "seen" when the disk is upside down;

Furnish those extra holes with a paper punch;

Buy and install a hardware upgrade from Scammers Unlimited (or whatever
that company calls themselves);

Keep an old drive around (what I do);

Use SpartaDos or some other OS that lets you use both sides of the disk
by using the drive in its native mode.

In any case, pretty much all existing SW will work in the way it was
intended on the 551.

1682. New Atari Home Video Game (Just a rumor?)

Newsgroup: comp.sys.atari.8bit
Date: 1988-11-23 23:26:01 UTC
From: al710@unh.UUCP
Message-ID: <773@unh.UUCP>
Source record: 116386
Cross-posted to: rec.games.video,comp.sys.atari.st,comp.sys.atari.8bit

I posted this message about one week ago, and received exactly
one response. Unfortunately, that response was not very helpful -- it
said only 'expect it with six months.' So, in the hopes that
the message was never fully distributed, let's try it again....

/****************** Original Message ****************************/

Has anyone heard anything about Atari producing a 68000 based
home video game system? Rumors flew several weeks back, but
I've heard nothing new lately.

Specifically, if such a machine does/will exist, I was hoping to get
answers to these questions, before I settle on buying a Nintendo
or Sega:

* How does it compare to the Sega, Nintendo, and Atari XE systems
available now? What are the specs for these 3 machines,
and what are they for the new, rumored Atari box? Along these
lines, what kind of input devices (light gun, 3D specs, etc.)
will be available?

* When will it be released? (Rough guesses -- plus or minus
1/2 year -- are welcome).

* How about cost and projected game availability (within, say,
1 year of release)?

Post or e-mail replies. I'll summarize if the response warrants it.

/****************** Original Message ****************************/

Any information regarding the machine's existence is greatly appreciated.

>_definitive_ answer to the question, "will Sublogic [ever] support the '551?"
>
This is indeed one of the aspects of copy protection which give it a bad name.
Since Sublogic seems unresponsive, I would pursue one of the following
three approaches, if I encountered this problem:
1. Adjust the drive speed to 288 rpm permanently, and hope that everything
else keeps on working.
2. if (1) does not work out, install some "enhancement" to the drive's
speed-regulating circuitry, so that the speed can be switched between
288 and 300 rpm.
3. Work on a software solution (i.e. crack the copy protection).
I am well aware that both (2) and (3) require a substantial investment of
time.

I am also quite appalled that any copy protection scheme should fail over a
4% increase in drive speed.

>
>I have no trouble reading and writing 256byte formats, e.g. PERCOM.
>
>Jim

This is indeed a problem. Even 18 256 byte sectors requires much shorter
gaps than what the original IBM specs call for.

So here is my question: We are told elsewhere that the SX551 disk drive spins
at 300 rpm, which leads to all kinds of other problems. How does it handle
enhanced density, or even the standard 18 sector formats? Does it run
the clock slightly faster? Does it cut other corners? Or is some black
magic involved?

While we are on the subject, does anybody know what the guts of a SX551
contain (cpu, rom, ram, floppy controller)? With all the reviews I have
never seen any answer to any of these.

There is no way to program a standard 1050 to format parts of a disk, although some of the enhancements may let you do so. If you want to format only the first n tracks of a disk, you can start a format, listen to the sound of the stepper motor, and open the door when you think it has gone far enough. Even with a disk drive which displays the track number, that takes a bit of practice to get it right.

With most electronic equipment, it is a good idea to theck the power supply first. Ataris are no exception. Beyond that it is very hard to diagnose such a problem from its symptoms. You might try to re-seat all cards and connectors, since the machine has been sitting around for such a long time.

1687. Re: hard disks and the 1200xl

Angelo Trivelli asks: >does Atari still repair 800's?

Atari lists the 800 as part of its exchange program. I don't have the list of the fees involved in front of me right now, but I don't believe it was very expensive. Essentially you return your equipment to Atari with the proper fee, and they'll send you a replacement unit. Try calling Atari's Customer Service department at: (408) 745-2367 and ask for details...

Before you do that though, you may want to check the connections on the main board... it the 800 has been unused for so long a time, there may be problems with corrosion on some of the contacts...

Turn the unit over and remove the screws holding the case closed, then remove the top of the computer. There are several screws securing the heavy metal shielding to the printed circuit board. Remove them, then remove the shielding (carefully!). Inside the shielding there are several smaller boards mounted vertically in sockets. Gently remove and replace each board to break any corrosion on the contacts and to reseat them in their sockets. Gently press any Integrated Circuits which are in sockets back down firmly into their sockets.

Reassemble the shielding and case, and try the computer again. It might be necessary to clean the contact edges of the smaller boards with a solvent to get the best contact.

If you're uncomfortable working inside the machine, you might be able to find someone at a local Atari user group who'd be willing to help out...

To Kit:

Yes, ICD sells one of the few hard disk interface systems for the 8 bit, but they were correct when they said it would not work with the 1200XL. The 1200XL does not have the BUS on the rear, so the MIO unit would have no way of connecting to the computer. Nor would the Supra system work for the same reasons. It is too bad, really, since the 1200XL had THE best keyboard Atari ever made (in my opinion...)

Just a note: if the demo version of Diamond is anything like the final version, no thanks! I run an Atari BBS in New Jersey, and I have had users upload both the demo version of Diamond and GOE. I found the GOE version to be MUCH better looking, and smoother running, than the Diamond demo. Perhaps this is due to memory limitations (which should be removed with the cartridge), or perhapthat is just how Diamond will turn out. I hope either one of them makes it, however, since it might spark more interest in the 8 bit computers as "Serious" machines.

Howdy... Got a good collection of stuff here:
800XL w/256K RAM (Newell upgrade), OmniMon, Omniview
1050 w/US Doubler
P:R:Connection and 2 serial cables (4 ft each, 25 pin)
R-Time 8 clock cart

Lots and lots of software, including Action! cart + toolkit,
SpartaDOS contruction set, MyDOS 4.1, 850 Express, etc.
A few InfoCom games, (Hacker, WishBringer, fresh out of the box.)

800XL has modified heavy duty power supply (new capacitors
and diodes, much heavier service rating.)

All hardware is in good working order. Most units have original
packaging, all have docs.

Also a couple books, including Mapping the Atari (with XL/XE info),
all of the Tech Ref book, designers notes, De Re Atari, others.

The entire collection is easily worth $800. E-mail to this address if
interested, or write me at:
1851 Lake Lila Lane, #C7
Ann Arbor, MI 48105

It's a very practical, useful system; I've just let it sit around ever
since I got my ST. If you like working with 8-bits, this system is ideal
for program development...

I'd like to sell everything at once (makes it easier for me) but if you
only want to know about a few items, make me some offers. Otherwise $500
seems a fair price for the whole shebang.

Re: modem via joyport
Summary: Thanx, now can anybody help me ...

Gil Kloepfer <Gil@Limbic.uucp> stated that a program called
"Rhandler" exists and is a driver using device name "R:"
to perform serial I/O via the joyports on Atari 800 etc.
I am trying to locate this program or anything similar so
that I can connect a modem thru the joyport. Is this program
public domain and if so does anyone have a copy of the
thing? Thanks in advance.

Also, thank you, Gil for your clue.
Charles Green also suggested a way to do this via the SIO port without
extra hardware but I prefer to do a little soldering if it lets me use
an existing driver and thus avoid writing a lot of code which I am
not set up to do at the moment.

Cross-posted to: comp.sys.atari.8bit,rec.games.programmer

Several years ago, a computer games magazine entitled "Softside" published a listing for a game entitled "Deadstick" which was written in Atari Basic. "Softside" no longer exists, and I would be interested in obtaining a copy of the "Deadstick" listing so that I could translate it from Atari Basic over to a generic Microsoft Basic so it could run on the Mac and the PC. Now I know there are excellent shuttle simulators available (Orbiter for the Mac, for example) but I would still like to translate "Deadstick" over to my Mac, so that I can learn how one of these simulators is designed. Naturally, once my translation is finished I would make available to any and all gratis.

So, if you have a copy of the "Softside" issue containing "Deadstick" I would really appreciate it if you would contact me.

Thankyou,

Michael

While we're on the subject of dead equipment, I've got an 810 that hasn't been working for over a year now. The problem is that it just isn't getting power. When you turn it on, nothing happens. I know the power supply is ok, because it works with my 850 interface. I also did a continuity check on the on/off switch and that was ok too.

Does anyone have any clues as what to look at next? I don't have much of a clue when it comes to hardware, but my roomate is a hardware hacker and could probably help me out. Any help would be appreciated. I would rather not pay Atari $$$ for an exchange when I could probably get a new XF551 for almost the same amount.................

> information on both sides would still have to be flipped over to work
> properly. Sorry!

This is somewhat misleading to anyone who has no understanding of
double-sided disk drives. From the standpoint of "true" double-sided
operations, the XF551 does NOT write the 2nd side in reverse; flipping
a floppy writes it in "reverse." Flipping floppies has been the
method used by 8-bit Atarians for using the 2nd side of a floppy,
but it is only a standard (sort of) in the Atari world. (Unless
"Commodorians" and/or "Applites" or other single-sided drive users
do this too? I don't know about other 8-bit-computer disk drives.)

If one has an XF551 drive, and wants the 2nd side of a floppy to be
usable in other drives, then the solution is to flip the floppy as if
the drive were a 1050, except that the floppy needs to be punched with
a 2nd set (1 on each side of the jacket) of timing holes (I recall
reading that the XF551 uses those timing holes when formatting
floppies, just as the Percoms do. No, I never got into punching new
holes in my floppies to use the 2nd side in my Percoms, but now that I
know it will work.... maybe I'll try it, carefully!)

Over the weekend, I downloaded transcripts of two real-time conferences held on GEnie. One was with David Sullivan (aka Total Control Systems--about GOE), and the other was with Allen Reeve (aka Reevesoft--about Diamond)

For anyone interested in getting a graphics os I suggest reading these files (I'll be happy to send them to anyone--they are fairly long for posting. I also have the demo for GOE; which, at this time, only works with Sparta-Dos--I didn't/couldn't download the DOS 2.x driver)

Anyway, 1) Does anyone have the DOS 2.x driver for the GOE demo? and...
2) Does anyone know of, heard of, or seen more information about these two beasts?
3) Anyone review both and have a favorite?

Well it's been well over a year since I tried to do *any* programming on my 800xl, and now that I decided to try something, I find I need some major help from all you bright people out in netland. In its simplest terms my problem is this - how can I *read* data coming over the modem. Sounds like a dumb question? Okay, here's my dilemma. I need to have the modem answer the phone, connect to the machine that's calling me, and then wait for that other machine to send a specific string of text. When it does, I want my machine to send a reply. At this point, I have 2 out of 3 parts to the problem solved. I borrowed a subroutine from a BASIC term program that answers the phone and connects just fine. After playing around with XIO calls and consulting "Your Atari Computer", I found the way to send data just fine (or so my friend at the other end says :-), namely:

```
OPEN #3,13,0,"R:"
XIO 40,#3,0,0,"R:"
PRINT #3; "Here's my Data!"
```

Okay all you Atari guru's...how do I READ data now. "INPUT #3,A$" doesn't do anything (I can see by the modem lights that data is being sent, but the string always ends up empty). "GET #3, A" results in either nothing, or the letter "Q" (ascii #81) no matter what data was being sent.

I realize that I must be overlooking something with the XIO stuff, but that cryptic XIO command has me so confused! I also realize that the slowness of Basic is probably a factor, but I only need this to work at 300 baud, and if need be I would hope that compiled Turbo Basic would be enough to cover it since the *only* thing the machine needs to do is sit and read characters being *typed* over the line. Any help is both desperately needed and *greatly* appreciated. Thanks a lot all.

|>how can I *read* data coming over the modem.

You are reading properly. You can use GET or INPUT to get data from a port opened in concurrent I/O mode (this is what the XIO 40 and the mode 13 in the OPEN statement do).

|>OPEN #3,13,0,"R:"
|>XIO 40,#3,0,0,"R:"
|>PRINT #3; "Here's my Data!"

This looks fine.

However, saying you saw the modem lights blink doesn't necessarily mean you sent the data out the proper way. The baud rate needs to be set for the port, as well as stop bits, etc. This is a group of XIO's that you can get from "Your Atari Computer" (good book, BTW) or from the 850 interface manual.

|>Okay all you Atari guru's...how do I READ data now. "INPUT #3,A$"
|>doesn't do anything (I can see by the modem lights that data is
|>being sent, but the string always ends up empty). "GET #3, A" results
|>in either nothing, or the letter "Q" (ascii #81) no matter what data
|>was being sent.

You might be getting something back, but if the interface is at the wrong baud rate, you'll get garbage. Check this out.

Next thing you will ask (as I did) is how to check if there are characters waiting in the input buffer to be read. This is so you can go off and do something else until characters are ready to be processed. The following code will check this:

```
STATUS#3,X
A=PEEK(747)+256*PEEK(748)
```

A will contain the number of characters in the receive buffer, or zero if none have been received yet. The STATUS command is important. This is in my 850 manual page 29.

Getting serial I/O to work on the Atari is almost like an art -- there's lots of restrictions and options to deal with -- getting them all to work the right way requires patience, and a locally connected terminal handy. I hope this gets you (and others) started, but it's not nearly enough to solve the problem.

Jeff Donsbach asks about a Dead 810 disk drive that doesn't seem to be getting power.. power supply tests OK...

You might want to (carefully) remove and replace the "side board" in the 810... it's the PC board mounted vertically on the left side of the drive mechanism (it's secured by a screw in the front, and another in back). The power flows from the jack in back of the drive, through the sideboard to the power switch, then back to the powersupply in the back of the drive. The contacts on the sideboard may have oxidized since the drive hasn't been used in some time... removing and reinstalling the connectors may help...

Incidentally, the Exchange fee for an 810 is quite low (can't remember exactly what it is just now, but it's nowhere near the cost of a new XF-551), but you would probably be far more happy with the XF-551... it's faster, smaller, and stores four times as much on a single disk..!

Source record: 116259

11/30/88

Some of the early 800's had solder instead of gold on the board edge connectors. An attempt was made to slow the oxidation period by placing Lubriplate grease in the connectors. Starting and other intermittant problems have been traced to oxidation on board contacts.

To alleviate the oxide problem, open up the computer and look at the contacts to determine if they are solder coated. That includes the CPU board which is buried under the casting. Whether solder or gold coated contacts, scrub the contacts with a dry facial tissue and re-insert the boards.

If the problem is not related to oxidized contacts, then try a couple of things in an attempt to isolate the problem. I will assume that 64K of memory chips is installed.

Pull the two high memory boards and turn off the disk drive. Turn on the computer with BASIC installed and type in a simple program to set up a "RUN" routine. If everything goes well, install the next memory board and repeat the test. If the first test failed, switch the memory board with another and repeat the test. Should this test fail the problem lies in one of the following areas: CPU board; 10K ROM; BASIC cartridge, or chips on the main board. Each would have to be checked by substitution with others.

Parts for 800 machines are available from sources listed in Analog and Antic.

I hope this discussion leads you to a solution to the problem.

Wanted - 800 XL (with the Rev B keyboard. Has "tall" keys and a sort of pebbled surface on the keycaps) and a clean, working 1050 drive.

This is for a friend, strictly for entertainment. No "extras" are needed/ wanted.

Will pay around $160 for both (the going rate in mid-michigan)

Additional features, again, while not wanted, will help make the sale at that price. The "crummy keyboard" machines are going to need to have something really wonderful to make up for the awful keyboard.

Speaking of good keyboards - Howard's XL he has for sale has one: I know, I went through a bunch of BS to get it for him!
(Howard: Hpope you like the J.T. keys better! Personally, this Amiga 2000 kicks. All it takes is money...)

Interested parties should leave a message on my Lansing BBS, The Club, at (517) 372-3131. Uninterested parties should call the Club II in Detroit, as I just received the usage reports and the 8 bit crew there is well managed and hoppin' (313) 334-8877. The Club II still has the life history of memory upgrade software online, including 1 huge ARC file that is the combination of everything we've ever recieved.

With memory prices the way they are, will upgrades ever be the same?
Still, well worth it to stick Japan for it's insane trading policies.

If you've ever taken the connectors apart (and probably if you haven't),
you may have some corrosion on the pins. This happened a number of times.
A combination of contact cleaner and a little sandpaper cured it.

>my 850 manual page 29.

Okay, a related question: I'm trying to print out a large string through the modem, while scanning for any keys that the reciever might send in during the process (sort of like a "hot keys" feature on some BBS's). I use the following code:

```
10 READ A$:IF A$="***" THEN RETURN
20 ? #3; A$
30 STATUS #3,X:IF PEEK(747) THEN GET #3,X:RETURN
40 GOTO 10
```

Now, by your explainations (and all the documentation I've seen), this should work fine -- When someone presses a key, the information will stop after the last string, and X will contain the ATASCII value of the key pressed.

Problem is, when the reciever presses a key, it gets "buffered". If you whack a key when the first line is displayed, the character won't get processed until several lines further down. Also, the slower the baud rate, the worse the situation gets -- 300 baud is almost non-responsive, 1200 baud requires a few seconds, and 2400 baud is acceptable.

What am I doing wrong, and how do I fix it?

>Has anyone heard anything about Atari producing a 68000 based
>home video game system? Rumors flew several weeks back, but
>I've heard nothing new lately.

The only new thing that I have seen from Atari lately is the 7800. I saw this at a Federated, selling for $150 or so. It had a real joystick as opposed to the touchpads that Nintendo has. Federated also had a good supply of cartridges for it. Can't recall any names off hand but there was at least ten different names. What I liked about it is that the 7800 would also take the cartridges for the 2600. So now I can use all those old games that have been sitting around. I haven't bought it yet. I'm not quite sure if I want to or not.

I was wondering if anyone out there has already bought one and can tell what it is like. Any rumors? Comparisions to Nintendo or Sega would be good.

Thanks,

Mike Kazmierczak

The newest game system Atari has out right now is the new XE game system. It's called that because it's based on the XE computer. In fact, what it really is is a 65XE CPU with a detachable keyboard. They rearranged a few things outside, but it's the exact same internal stuff. In fact, if you open it up, you can see where the 4 function keys went because the "ports" are still there. It can use a drive and everything. What they did was to market their computer line but sell it as a game so the younger crowd will buy it up more. They have them at Toy's R Us and such and they're not to bad. It's a home computer in a video games clothing...

The 7800 was designed while Warner Brothers still owned Atari and almost
never saw the light of day. Tramiel inherited 100,000 or so of them when
he bought the company. They sat for a year or more and were only released
because Atari wanted to clear them out and make a little money (my opinion).
They caught it just right though, because video games took an upswing about
then. The 7800 has even better graphics than the 8bit computer (and XE Game
System) because it was designed with graphics in mind and with a better
graphics handling chip. I think they compare very favorably with the
Nintendo and Sega systems, but have only a limited number of cartridges (if
you don't count the 2600 games). What irks me is that some games like
EPYX's Winter Games are available for the 7800 and not for the XE GS.

BTW, $150 is way too much. I don't remember the exact price but Toys R Us
and Child's World are selling them around here for under $100.

Pardon my butting in, but what is this program you're discussing? Which types of Atari formats will the program transfer to PCs? Old single density, 1050 "Enhanced" density, true double density, or some other, newer format? I have an 800XL, Indus GT, and also a PC compatible, and it would be VERY nice to be able to transfer files just by copying to disk. What is this program called?

>you don't count the 2600 games).

I agree, the 7800 would (have been?) be a great system if there was more
software for it. As it is now, Sega and Nintendo seem to have a deadlock on
the "hot" game titles, which seems to hamper Atari's chances to penetrate
the market.

In relation to all this, who else thinks as I do that Atari is spreading
itself reeeeeeeeeeeally thin with three game systems? Why the 7800, the 2600,
and the XEGS -- all at once? If all the software was compatable, then it'd
be okay (sort of like Nintendo's Basic System and Deluxe System, etc.). But
with incompatable games, it's like a lot of waffling from Sunnyvale...
Maybe just the XEGS and/or the 7800.

Then, of course, this all ties in to the problem of Atari's "Pac-Man"
image problems in America. When will we see a serious drive for promoting
the ST in America? Us ST owners know the machine blows the doors off most
other machines in its price category, but all we get are silly looks from
the die-hard IBM/Macintosh pinstripes crowd...

Anybody want to add anything to this mess?

Yes, the 7800 has a great architecture because it was designed with coin-op
mentality, making it terribly difficult to program, which is why Super
titles haven't exploded onto the market. It has great potential to beat
Sega, and give Nintendo a run for it's money. Yes, if you want
"Arcade" titles, you can buy a Sega/Nintendo, but if you want new, neat,
good graphics, good playability games, the 7800 _should_ be the machine,
it just doesn't have the software base yet. Ideally, the new popular
7800 titles would become the Arcade Games of the future, becuase they'll
have been desgined on a machine that permits _somewhat_ easier portability
to an upright (at least, that's an idea). (Did you know that the ST was
used to design the shapes in Gauntlet II??)

>Maybe just the XEGS and/or the 7800.
>

No, Atari isn't spreading itself thin with 2600/7800 & XE systems, remeber that the 2600 is still selling like mad, along with the games, and Atari doesn't have to do much to make money there. The 7800 is it's "new" machine, which _is_ backward compatible, so you buy the 7800 and you get _all_ the hundreds of 2600 games (which is the Basic/Deluxe idea).
Now the XE system is the logical extension for the 8bit Atari line, which already has a huge installed base (like the 2600, although not nearly in the same numbers), and the XE _Game_ system plays / uses all the older Atari computer software, hardware, and cartridges. So by bringing out the XE (which used to be the 400/800 looong ago), Atari can make use of all sorts of existing machines out there that people are selling, or have sitting in the colset, as publicity and perifs. The XE Game system is a Computer & a Game Machine, an a _proven_ computer (i.e. education and fun).

So really, you've just go two lines, the Computer Line, and the Game line, both marketed under the Game image, because now Atari's selling the ST as it's flagship computer.

Does anyone know were I can obtain any programming languages for the Atari?
I currently am using Turbo BASIC XL(boo hiss) and I've TRIED a little Assembly.
I am interest in other programming languages such as C, Fortran, and Pascal.
My other concern is that I don't what to spend tons of $$$$ for them. I have
heard that ANTIC mag others a C compiler for around $25. Has anyone else heard
different?

Say BJ,

If you need a beta tester for your SUN/ST Emulater, I'll be more
than willing to work out an arrangement with you.
Now, in reference to your article, I agree with you on the image Atari
hasn't been able to shake yet. I can't stand it when some IBM/Mac user
refers to the ST (being an Atari product) as a game machine due to
Atari's advertising strategy with it's games division. I for one will
surely be glad when the ST commercials hit the airwaves. I've seen a
few on the local cable channels, but there's not much of an audience
there.

Don't bother with Deep Blue C (the one offered by Antic); it is an antique.
Since it came out there have been two public compilers, Ace C and CC8, that are
much superior. Ace C comes with a complete linker package, but CC8 is a much
better compiler. You best bet is to get CC8 to compile your C programs and
Ace C to link them. There is also Lightspeed C, but I haven't seen it and it
costs money.
Don't bother with Fortran. I have never seen it for the 8-bits and it is
an awful language anyway.
A friend of mine gave me his copy of the Atari Pascal Development System,
and I quickly found out why: it is a piece of junk. Compile a 5 line program
and you end up with an 80-some block file which you then have to plug into a
runtime environment. It just isn't worth it. You might look into Kyan.
If you want to do Atari-specific programs, you might try Action!. I have
never used it, but I have heard lots of good things about it.
A while back, the author of CC8 contacted me. Since then, I seem to have
lost his address. If you (the author) are reading this, please drop me a line.
I would like to talk to you about something. Thanx.

It's also got some pretty reasonable games, plus built-in BASIC etc.
And right now there's a $50 refund from Atari going on, so you can get
the whole she-bang for under $100 - includes light-gun, a couple or more
games etc etc. What really hurts is that I bought one at employee (ie dealer)
price for my littl'uns and now Price Club (a local discount store) and
Toys r Us have it for much less!

FYI, and to correct an earlier posting I saw, the other two game systems are
the 7800 which retails officially at around $79.95, and the 2600 at around
$49.95. Both can be discounted (and are!).

Note also that Atari cartridges tend to be much lower cost than some of
the "others", which means that you get more variation for a fixed amount
of 'pocket money'.

I think that's "Deep Blue C", which I have a copy of. For $25, its a pretty
good deal. It's a subset of real K&R C, and has some draw backs (comments are
some non-standard character combos that I can't even remember). And it compiles
slower than anything. But, as far as I know its the only C game in Ataritown.

There was a language that was kind of a cross between Pascal and C called
Action! from (I think) Software Tools, Inc. That was BY FAR the best language
product I ever saw for the 8 bitters. The language was on a cartridge.
If you can find a copy of Action!, by all means grab it.

Fortran? I don't think so. Whocaresanyway?

Good luck.

The Atari 7800 system has two buttons. The XE system has one button, which seems to work just fine, and has never bothered me -- does anyone else care to comment on the merits of more buttons? How about the merits of different control mechanisms...

1728. Back Issues of Zmag/ST Report

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-07 00:18:02 UTC
From: gdtltr@vax1.acs.udel.EDU
Message-ID: <2465@udccvax1.acs.udel.EDU>
Source record: 116281
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

Handling the mailing list has turned out to be ok, but handling requests
for back issues has turned out to be a royal pain.

Partial solution: back issues will now be made available for anonymous FTP
at louie.udel.edu in the directories pub/strp and pub/zmag, respectively.
I know this won't help the UUCP and BITNET (I think) people (which probably
make up half the list), but it will help.

Gary Duzan
Time Lord
Third Regeneration
Atari Enthusiast Extreme

p.s. All the back issues I have should be there now. I am told that it is
ok to put them there, but I'm not sure. If anyone looks there and can't
find them, let me know. Thanx.

I am a SpartaDOS 3.2 user, and run the Carina II BBS software for my board, Freestyle. I am interested in the develoment of ICD's SpartaDOS X cari specifically, how compatible it will be with Sparta 3.2 (not very, I am afraid!).

[Freestyke runs on a 130XE (unmodified), 256K MIO, two 10meg Tandon hard disks and a hayes-compat. modem.]

Any news on the cartridge, or any of ICD's other products, would be much appreciated!

That remark certainly does not apply to any of Atari's systems, since they do have the capability to support much more complex game controllers. I have been collecting parts to build myself an analog stick with up to _5_ buttons! Of course, it won't work without software to support it. So, when (or if) I finish that stick I will write my own games for it. Along the same line, I'm sure if some manufacturer markets a new type of stick, there would be enough incentive for writers to develop games for it. Now all we have to do is to find enough incentive, as in software support, to produce the stick in the first place. (catch-22!)

One solution is to bundle some initial set of software with the hardware, a la Koala Pad. Just start the ball rolling and watch it go.

On another note, for those who prefer digital sticks with multiple buttons, the analog pins could simply be fed digital button-down signals. They can't be latched (at least not on the XEGS), but that's not that serious, is it? Also, the second stick port could be used exclusively for the extra buttons. This has been done already, I believe, on Star Raiders, using a keypad. The possibilities go on and on...

Now, tell me again about not supporting multiple-button complex games.

My thought on the matter (admittedly I haven't tried any of the newer game systems) is that I don't see that you can have too complex a control system in a handheld unit (doesn't include keypads (as per star-raiders)). I mean, a few years ago I bought the Atari trackball, but later took it back. It just didn't seem to work well from my lap, nor did it have enough mass to sit still on the table. The joystick is going to have the same problem-how do you do a good job of dealing with multiple buttons if you've gotta hold the thing at the same time. I realize that some of the newer game setups have all sorts of fancy consoles, but don't a number of these come with the game, not the system? And that spells money. Not trying to be cheap, but I AM a grad student.

Sure, I'll make a comment. I definitely prefer the feel of the old "standard" one-button stick that's been around for years. I find it much more useable than the control pads of most game systems. As for the one-button argument, it's true that some games need more than one button for good game play.....but that's no problem (or shouldn't be) ....the XEGS comes with a keyboard. It's been the standard with Atari 8-bit software for years and years to use the stick for direction and firing, and including the tap of the space bar for smart bombs or whatever.

If you mean "Do I read this" then sure, whenever I get it. It has been rather infrequent lately. Actally, now that I think about it, I do have a couple of questions on the tried but trusted 8-bit...
1) Does the Dataque 816 upgrade support the 800? If so, when will it be released, how much, and will I be able to have a huge box of about 8 meg of ram sitting behind my 8-bit?
2) How does one go about setting up any graphics mode above gr.4 in OSS' 'C65'? I get a function implemented return, but no constant screen display. It's annoying.
3) Where can I find data about the Indus GT disk drive? It has a Z80 cpu inside it, and the potential of redefining disk stats and running small programs, but I don't have the faintest idea of what the various locations do, nor indeed, where they are. Does any one know anything about it?

Thanks in advance,
Bob Nigh

Yes, I care to comment. Although I don't have much experience with multi-button joysticks to compare it to, I have found (in the 8 years [I can't believe it!] or so that I have been playing with Atari 8-bits, and briefly tried 2600 and Intellivision) that one button on a joystick is quite enough. I feel that in the "heat of battle" (assuming a fast-paced video game, which most seem to be) that I would tend to become somewhat confused with > 1 button. (3 buttons on a mouse seem to be too many for me, although I'm again not a vastly experienced "mouser". This would especially be true if there were no commonality among video games in the way that they used the joystick buttons. "Which one is the fire button in Zorgblaster, again? I forgot."

About other control devices: I am seriously thinking about spending $10 or whatever for a reconditioned Atari (or after-market) Trakball. What would I do with it? Well, maybe use GOE or Diamond in "mouse mode!" It should work, since (I have been told by Matt Ratcliff, an 8-bit "expert") Missile Command in Trakball mode works with an ST mouse! (Some people think, and they may be right, that the Trakball needs a small [?] modification to work like an ST mouse... talk/net to/with the Michigan Atari Magazine folks... I don't know for sure who's right.)

I have a Koala pad (which I bought used from a local "defector"-to-Macintosh) with one button in really bad shape - so I just use the other. It works a bit more clumsily for me, and I will fix it one of these days (sure, eh?) but overall, I like it. One can build (I read in ANALOG about 2 years ago) a Koala-pad-emulation joystick (a proportional joystick) for the 8-bits, out of a R-Snack joystick pot.

and a very few parts (resistors and ?) I have not tried it, but one of these days.... (If it would only work with Flight Simulator - I refuse to pay whatever-it-costs for a custom proport. joystick for FS2, when I can barely fly the thing [splash! or, at DuPage airport, crash! I can't land it].)

On my Christmas wish list is a light gun (probably a Sega gun modified to work with the 8-bits, better, I hear, than the Atari l-gun) and a game to use it. (So far, that == Barnyard Blaster, if only Crossbow would be out sooner!)

I've said more than enough for now (and maybe for quite a while :-). See you at your Atari dealer (:-).

Ric,

SpartaDOS X should be completely compatible with SpartaDOS 3.2 in all
but very minor points. I do know that, in current form, Carina II
will NOT run with SpartaDOS X. However, Jerry Horanoff is just about to
release a new version of Carina II that will allow the use of SpartaDOS X.
One main advantage to this is that you will get approximatly 5K more
programming space in BASIC. This new update is, according to Jerry, to
be released "within 2 weeks".

I also run a Carina II BBS, and I am always interested in hearing from
other Carina II SysOps. If you are likewise interested, give my board
a call at 201-938-6906 (NJNEW through Pursuit) and we will CHAT...

I recently have run into a problem, after not using my old upgraded
400 for a few months. I tried to write a program in BASIC on the
old standard BASIC CARTRIDGE. BUT! If I put a statement requiring
any mathematics at all, the program freezes up. SO what I was wondering
is if anyone else had this problem, and if so how did they fix it.

My guess is that the EPROM's on the cartridge have some how been altered.
Thus a possible fix would be to re-burn them. (Or just buy a new
cartridge)

Now Problem #2.
A few years ago, I got a good deal on a touch tablet for the atari.
It is one made by CHALKBOARD INC., I have one software cartridge
for it and wish I could develope some more. (The name of this tablet
is the Power Pad.) Of course the company folded, leaving me with no one
to contact. If anyone has an idea of how the thing might work, or
who to contact about it, I would appreciate some mail.

Nice to see another Carina II SysOp on the net! I ran Carina I from two years and then went over to Carina II as soon as that came out. My MIO is currently being repaired at ICD, so my board is temporarily down. I used to run it as Phantasmal Alchemy BBS before I came to school, but I have since changed the name to Memory Alpha.

I have spoken to Jerry Horanoff many many times and know him quite well. Because I knew Jerry well, I beta-tested Carina II for him (along with a few other people). I am also Co-Author of the RoboWar II program Jerry offers with Carina II. Jerry now works for ICD and he has given me a lot of information about SpartaDos X. Jerry got his hands on a beta-version of the cartridge and he has made Carina II compatible with it. I have yet to order the Sparta X (I am a poor college student), but I do know a bit about it. It's a 64K cartridge that only takes up 8K of memory in the computer. It is in the same casing the R-Time 8 cart is in, so you can plug another cartridge on top of it. You can get a directory of the cartridge like you would of any drive.

I have a lot more information on it, if you'd like. From what I understand, Jerry has plans to make Carina II compatible with the XEP80 (which I am fortunate to have). The networking should also be finished by now (I have an earlier version of networking that only works with message areas). Jerry plans to release the new version of Carina II free for registered Carina II owners within a few months time. I'll let you know more as I hear more myself.

The system I run consist of: 256K 800XL, 256K MIO, ADaptek 4000a, Seagate ST225, Microscience 20meg drive, R-time 8 clock cart, INCOMM 2400 baud modem, and other misc. equipment (lots that isn't used on the BBS, such as 3 drives, 2 other 8-bit computers, etc.).

Re: The touch tablet and how to use it:

If this is at all like the Koala Pad, then it is read just like the paddles (i.e. one paddle corresponds to the x-direction and the other corresponds to the y direction, the left button is one paddle buttonm and the right button is (obviously) the other. If your touchpad plugs into the joystick/paddle I/O db9 connector, then it most likely works this way. Try reading it like a paddle and see.

Good luck!

I represent a small, select group of indiviuals who undertaken a very large project. We are a group of hobbyists/BBS operators who have banned together to create one of the largest NETworks consisting entirely of Atari 8-bit computers.
We are looking for people who are interested in joining this group.
There are currently 14 BBSes linked together in this NETwork.
We are using BBS Express Professional which provides NETworking similar to that of FIDO net. Anyone currently using this program or thinking of using it in the near future and interested in helping us expand our boundries please contact me.

We are particularly interested in Nodes outside of the USA and over seas.
Key loacations would include the UK, Australia, New Zealand, But we're looking for Nodes from all over.
Other areas of we need contacts from are West Canada and Mid/south USA.

One button joy sticks work just fine for any joystick controlled game.
In reference to "reasonably complex", I contend that a keyboard is
necessary for truly complex games, hence the XE is the clear winner.
In addition, you can put a disk on an XE, giving more storage (I am
playing Alternate Reality right now - six SSSD disks) and the ability
to do game SAVE, an important option for long, complex games.

Al,

I remember seeing your name on the title screen of RoboWar, as well as on Jerry's board.

I downloaded the new Carina II update last night from Jerry's board, but could not get it to work as advertised. It kept locking up in different areas, and the functions listed in the README file were not working as they were described. I will try messing with it again, because I want to be able to use the Networking when it is FINALLY available. Do you know when Jerry is going to get it out? Now that 2.2 is out, I assume he has more time to work on Networking (which I REALLY want!)

From: arrom@aplcen.apl.jhu.edu
Message-ID: <356@aplcen.apl.jhu.edu>
Source record: 116205

Would whoever wrote the PC files to Atari program please send me
a copy of the program with the write-binary-flies-from-pc-to-atari
bug fixed? I don't have access to a way to compile the thing with
the fix myself.

Source record: 116206

Eric & Al, plus any others.... I use PC-Pursuit (as I am sure many of you do), and while reading on the Net Exchange board, which supports PCP, there was a note to the effect that networking through PCPursuit was illegal, oir at least went against the TELENET contract. They claim that using the net to redistribute other messages in effect forms a new network, thereby extendin a single password to all the readers of that net. Sounded strange to me...

What are the legal guidelines for networking?

1753. Home-grown controllers/interfaces

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-13 00:05:23 UTC
From: RCH@cup.portal.com
Message-ID: <12546@cup.portal.com>
Source record: 116207

Has anyone made/built/otherwise devised, any home-grown controllers, or built interfaces for their joystick ports? I read both ANTIC and ANALOG magazines, and every now & then someone will writ an article showing how to make a parallel printer port with the joystick port. Or use your old 800 as a print buffer.

Remember the old AtariLab kits? I never saw one, or got to play with them, and wondered if 1) they were still available? 2) they were worth bothering with? 3) were improved to real-world interfacing, such as the recent X-10 remote control power modules that have long been available on the C64 and Radio Shack Coco computers....?

I am looking for something that will allow remote control, security system applications, equipment monitoring, etc... Thanks for any mail or postings!

1754. Atari 800 system expansion make sense?

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-13 01:12:24 UTC
From: david1@mhuxu.UUCP
Message-ID: <8845@mhuxu.UUCP>
Source record: 116208

A friend who has an 800, but no other peripherals, wants to expand his system so he can use it to keep track of his inventory of various personal items as well as wordprocessing. I told him a disk drive and printer will cost him around $600, plus more for software. What I didn't know to tell him were the following:

What printers do you think are good recommendatons?
Would he need the infamous 850 interface for one or are some direct-connect?
If they are direct connect does the cable come with the printer?
What do the recommended printers cost?
Possible suppliers? Suppliers to stay away from?

What about disk drives? I have a 1050, but which other ones are recommended? Cost? Suppliers?

I know there's not alot of software around. I guess he needs a database manager for his inventory needs. Which are available and from where? Also which word processors are good? Is Atariwriter decent?

Thanks for any info you can supply. My friends alternative is to buy an entirely new system which I thought would end up costing him $2000 for everything he wants. Am I off base on this cost estimate? He was considering an Apple 2C or an IBM type.

His 800 has 48K.

My appologies, I didn't get a chance to complete my last message.
(still getting used to Portal's format)

As I was saying, We are looking for anyone Currently running BBS Express
Professional! or are thinking of running it that would be interested in
becoming a part of a NETwork.

So, if you are interested or know anyone that might be, get back to me here:
Bruce_A_Webbe@cup.portal.com
or contact me on my BBS : 408/226-2889
in San Jose, California.
I would appreciate hearing from anyone with information or leads in this
endeavor. If need be, just let me know where I can contact you.

Thanks in advance.

1756. Financial aspects of new 8 bit software

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-13 02:55:43 UTC
From: daryl@ihlpe.ATT.COM
Message-ID: <3916@ihlpe.ATT.COM>
Source record: 116210

I am curious about the aspects of software production for the 8 bit ATARI machines. As we all know, there is a considerable lack of new software for the 8 bit machines. However, there seems to be continued new software for apple, C64, etc.

It seems to me that once a piece of software is developed for the other 6502 machines (especially the C64) that the conversion to the XL/XE machines would be fairly easy. Surely there are a lot of us professional types that would be interested in doing something like that.

The question I do not know the answer to is what is the pay back for converted software? How much would the original author get? How much would the converting author get? How many copies would need to be sold to at least break even for the effort?

There are a lot of 800's, XL's, XE's, and XE games out there. I can't believe the market is not there.

I have done a tremendous amount of work on Carina II in the way of modifications. Jerry and I came very close to releasing a utility disk for CII but once I got to school, my MIO broke and I haven't yet received it back from ICD. Once I do, and get my board back running, I will be working full speed on the utility disk. here are some of the programs I have written already that will be on it:

o A program to automatically delete accounts by their age, in either days (say, accounts 60 days and older), or older than a certain date. Carina 2.2 (just released by Jerry) already has a few mods I have done, including the [M]ark Permanent feature that prevents anyone a SysOp marks Permanent from being deleted. What makes this program useful is that it can be run from the BACKUP.BAT file as well as interactively.

o A program to print that prints the password file to the printer in a very nice formatted ouput. I went all out on this program, and in addition to the many options you can change, it also prints two pages of BBS Statistics after printing the users (or, you can simply print the Stats by themselves if that is all you want).

o After seeing a couple of 'Top 10' programs come out, I wrote one of my own. Again, I may have added TOO many features, but just use the ones you want! You can have from the Top 5 to 30, toggle which areas it collects stats for (Posts, uploads, downloads, and Calls), and also have it print all sorts of BBS Stats. I wrote some ML routines for this program to make it as fast as the other Top 10 programs (Mine does a heckuva lot more!). This program can also be run from the BACKUP.BAT file.

o Ever want to add or delete keywords in a file area? I wrote a program that allows editing of any file area's keywords, including those areas that do not even have key words. A SysOp can change the keywords on the entire BBS, but a SigOp can change them just in his/her section.

o Ever want to delete certain voting polls? That is possible now also. It works similiar to the keyword program in that a SysOp can view the polls on the entire BBS, while a SigOp running the program in his section can only see the polls in that section. This has been implemented into the MAKEVOTE module.

o I modified the FILEVAL program so files (before they are validated) can be Moved (or copied) to another file sections. Often times, someone will upload a file to the wrong area, so this is useful. In addition, the description can be edited before the file is

validated.

o I wrote a SysMenu program which is now implemented in version 2.2 of Carina. This is a VERY flexible menu program that allows you to run any other BASIC program. It has a built in editor, and for each Basic program you set the description (as appears in the menu) and the filename (including path). SYSMOD has been modified slightly with an added keypress (M) that runs this program.

o For USEREDIT I added two new features. One, the [M]ake Permanent, I mentioned before. The second is a feature that allows you to [S]earch for new users. This is VERY useful (and fast) because New Users can occupy deleted records as well as being appended to the end of the password file and previously either the SysOp would have to keep track of which records he deleted, or go through the entire password file every once in a while to see if any new users slipped into deleted slots.

I know there are other mods, but it is too early in the morning to remember the rest of them. I used to run a Carina I BBS, Phantasmal Alchemy, in Connecticut. I had a tremendous amount of mods implemented into the BBS and available for SysOps to download. I felt kind of sad going over to Carina II and losing all that work, but I've made up for it with what I've done (so far) with CII. I intend to do more! I would guess that the utility disk will be out in late January, early February.

Oh yes, I mentioned that Version 2.2 is out. You can download that from Jerry Horanoff's board (Carina Headquarters) if you have access to his Carina II SIG. If you're a registered owner, tell Jerry and he'll give you access. The phone # is 815-874-1836. I talked to him for a while the other day (almost 2 hours Long distance! Ack!) and version 2.2 fully supports the XEP80.. If one has a TV and a monitor, you can have two different displays. One will be the Full Page user edit window, and the other will be the BBS. The Full page screen still uses 40 columns (because it uses display lists) and the other screen (what the users see) is in 80. Very impressive! (Almost looks like true multitasking)

Enough for now, I hope no one's fallen asleep.

Eric,

Jerry will be working on Networking and will hopefully have it done sometime in the next couple of months. I am pushing him for it, as he already has the most difficult part done (the actual calling of other BBSs, logging on, and sending a file). From what he told me, the message base networking is already done. I have a preliminary version of networking, but I have as of yet to try it out with another Carina II SysOp to see how well it works.

We were planning to put all the Networking mods on the utility disk, when that comes out. I am not sure if that is still Jerry's plan, although it would appear so. I'll ask next time I call him. Unfortunately, Jerry is not on USENET.

1759. Diamond Press Release

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-13 17:02:00 UTC
From: PARSONS@KSUVM.BITNET
Message-ID: <8812131713.AA17069@ucbvax.Berkeley.EDU>
Source record: 116213

Here is the latest word on Diamond, a graphical user interface for the 8-bits. This was downloaded from GEnie, and I assume that I have permission to do with it as I please as long as it is in original form.

My personal opinion is this: read the transcipts of conversations with the programmers (I will be happy to send them to anyone who asks), and wait for a cart-to-cart review (that is possible since both are in cartridge form now.) Both sound good, but the transcripts tell a lot.

December 10, 1988

Press Release: Diamond OS SuperCart

From: Alan Reeve/Reeve Software

Attention Atarians,

It has been a little over six months since our first press release for our Diamond OS. Since then a lot has changed. We initially intended to ship Diamond as a disk based product and it was to require at least 64K.
In August of 1988 we were contacted by Shelly Merrill of Merrill Ward & Associates. Originally Diamond was going to compete against their product, however, things fell apart with the developer and Shelly has been assisting us with the marketing of Diamond. We elected to unite as I felt that his marketing knowledge could greatly boost the sales of our product, and also create a resurgence of interest in the Atari computer. Shelly has since moved on, formed USA Media, and has been very helpful in the marketing of Diamond.
We shipped our disk based version of Diamond at the end of September. It did much of what we said that it would, however we have received many comments and criticisms regarding some areas. The most common complaint was that the disk version functioned solely with Atari DOS 2.0.
Since the release of our disk based version of Diamond we have spent the last ten weeks adding to it in order to create our much more powerful cartridge version of Diamond. The cartridge version adds a lot of power over

our initial disk version:

* Supports two windows on the DeskTop.

* Supports Quit to Basic and direct return to the DeskTop.

* Supports most DOS types (Atari DOS 2.X, DOS XE, and SpartaDOS).

* Supports folders (subdirectories) and time/date stamping.

* Windows have sliders, and fullers that support full reversing.

* It's on cartridge and consumes minimal system memory to function.

* Much more...

Diamond is also completely programmable. We initially intended to have a separate Programmer's Kit, however, along with the cartridge will come complete documentation for programming the environment...it can even be programmed in Atari Basic.

The disk version was also to have memory drivers and be followed up by many external applications. Due to our continued work on creating such a powerful environment we have delayed the applications until the cartridge was completed. We will now be releasing the applications and they will support the cartridge, however, Diamond Paint and Diamond Write will also include versions that support the 64K disk version.

We are now pleased to announce that the cartridge version of Diamond is 100% done and will be shipping very soon as we produce the cartridges. It will first be available to users that wish to upgrade from the 64K disk version, and will then be available in stores nationwide. Please contact us for more information:

Contact:

REEVE Software

29W150 Old Farm Lane

Warrenville, IL 60555

(312) 393-2317

or

USA Media

7810 Malcolm Road

Clinton, Maryland 20735

(301) 868-5494

GEnie ID: REEVE.SOFT

CIS ID: 71521,2200

The separate applications will be arriving shortly as Diamond acts as a very solid foundation for external programs. The first Diamond based program will be Diamond Paint. Diamond Write, News Station, Diamond Publish and more will follow. The first three are almost complete.

Lastly, we'd like to thank those of you that have been supportive of our efforts to revitalize the Atari community. I believe that Diamond is the most powerful program written for any 8-bit computer and will lead the Atari 8-bits into the 1990's.

We hope that you will join us and Diamond as your Atari 8-bit soars to new heights.

> software for the 8 bit machines. However, there seems to be continued
> new software for apple, C64, etc.
>
Survey's that I have seen show that a typical new computer owner purchases
a great percentage of his software in the first six months with dollar
spending dropping off dramatically after that. This indicates that
there has to be a constant supply of new owners to really keep the software
market healthy. Unfortunately, that isn't the case with Atari, except
for the XE Game System, and they don't seem to be buying many disk
drives. This means the best market is for cartridge based software.
Atari seems to be the only company willing to supply this market and
even they have been slow to bring out promised cartridges. I have been
waiting for six months for (to name a few) Crossbow, Crystal Castles and
Mean 18. If anyone reading this is going to the Winter CES next month,
try to find out what happened to all the software and try to find out
what new software is promised in the next six months :-) . I have
sent private mail to a couple of people at Atari, but never received
an answer.

> It seems to me that once a piece of software is developed for the other

>
If you want to take full advantage of the graphic capability of the
8bit (with the GTIA chip), there is a lot of work involved. Many of the
people who know the 8bit best have moved on to the ST or Mac and seem
reluctant to spend their time on the 8bit Atari. Word was that Origin
was looking for someone to do Ultima V for the 8bit but couldn't find
anyone. They have now stated that they won't be doing an Atari 8bit
version.

> The question I do not know the answer to is what is the pay back for
> converted software? How much would the original author get? How much
> would the converting author get? How many copies would need to be sold
> to at least break even for the effort?

I think the pay for such a job is fairly low and is an upfront
pay with no royalities for the programmer doing the port. It is the
software company that is taking the financial risk and few seem willing
to support the Atari 8bit.

> There are a lot of 800's, XL's, XE's, and XE games out there. I can't
> believe the market is not there.
>
I can state for sure that there is a market (although I don't know how big). I belong to a Users Group and we have a merchandiser at the meetings. Many 8bitters are buying older software simply because there isn't anything new to buy. What is new (such as some of SSI's war simulations) isn't to my liking. What bothers me is why doesn't some company that does support the Atari 8bit market bring in some European software. There wouldn't be any conversion work involved (unless it was written specifically for PAL systems, as some is now) and the only risk would be the shelf space and distribution work involved. Thunder Mountain was supposed to bring in Winter Challenge for the Atari 8bit, but I have never been able to find it and my source hasn't been able to get it from his distributor. I have written several letters to Access, Accolade, BroderBund and MicroProse with few answers and what I got was pretty terse and unencouraging.

The only encouraging words I have heard came from ANTIC magazine who state that they are trying to add to the 8bit catalog by bringing back more old APX titles and adding some out of production commercial software that they can find and being a distributor for small companies or individuals who still support the Atari 8bit. If you think this is a good idea, at least drop them a note and thank them profusely. And, by the way Daryl, they have had more ACTION! typein software lately (as has Analog). The January issue has an 8bit shoppers guide with 8 pages of software/hardware and the addresses of 65 companies that still support the 8bit computer (although some of their offerings are getting pretty old now). Some of the software ANTIC is carrying in their catalog are TurboBase form MicroMiser, Super 3D Plotter II from Elfin Magic, some Infocom text games, StickyBear software for kids, MIDI Track II and III from Hybrid Arts and AdvanBASIC along with the modules such as the Optimizing Compiler for it. I applaud their efforts and hope they are successful. It will only work if we 8bit users support them though. They have also had some very good and worthwhile software on their disks lately. A subscription with disk is only $59.95 ($5 per issue). An excellent deal. When my magazine sub runs out, I am going to get the disk option.

The AtariLab kit is still listed on the software list I got from Atari at
the Summer CES. It is listed as AED80013 and the Light Module is AED80014.
I don't think that any modifications have been made to it.

> I am looking for something that will allow remote control, security system
> applications, equipment monitoring, etc... Thanks for any mail or postings!

The latest ANTIC 8bit catalog contains the PowerManager from Terrific Corp.
for $24.95. This is the hardware and software necessary to use the X-10
controller in your home. It was reviewed in ANTIC an issue or two ago.
There was even a simple PD version in that issue of ANTIC, but the
commercial version is supposed to be much more powerful. On further
reading, I see that it says it requires the CP290 Powerhouse Interface
from X-10. I don't know what that costs or where you would get it, but
I imagine the same place you can get the X-10.

> The question I do not know the answer to is what is the pay back for
> converted software? How much would the original author get? How much
> would the converting author get? How many copies would need to be sold
> to at least break even for the effort?

I'll try and answer this since I used to write programs (SynFile+, PaperClip, BackTalk, and Sherlock) for the 8 bits. I also worked with a several people who were converting programs to/from the Atari 8 bit systems.

As a general rule an author gets about a 10% to 20% royalty on software he writes. It varies based on market size, how well know the author is, past hits, is it a game or an application, etc. That royalty is on the publisher's selling price which is usually about 45% to 55% of the the retail price. So a program that sells for $39.95 will wholesale for about $19.98. The author will get 10% of that or $2.00. On a conversion the original author and the conversion author will split the 10% royalty, usually 50-50. So each will get about $1.00 per copy sold.

Depending on the program being converted it will take between 3 and 9 months to convert a program from one 6502 machine to another. Applications usually can be converted fairly quickly since they don't have any fancy graphics, games take longer due to the graphics.

So to make a conversion worth doing the converting author must be able to make 1/4th to 3/4ths of a years income off the conversion, depending on the amount of work required. If he expects to make $30,000 a year he needs to make $7,500 to $22,500 off that conversion. So he, the publisher and the original author all have to guess whether the program will sell 7500 to 22500 copies on the Atari 8 bits. Right now there are *NO* 3rd party programs for the 8 bits that are selling that well so it doesn't make much sense to port a program from a C64 or Apple // to the Atari.

NOTE: I'm completely ignoring the publisher's expenses in the above. Ads cost about $5000 for a full page in 4 colors. Boxes, disks, labels, etc. are about $2.50 to $5.00 per copy (depending on how fancy). So the publishers break even point may be higher or lower than the converting author's break even point.

Software publishers base a lot of their decisions on what machines to support on the SPA's reporting of software sales figures. They break software sales down by machine and type of software (business, games, etc.). According to the SPA the top 4 software markets are the IBM and clones, Macintosh, Apple // family, and the C64. All the other computers (Atari 8 bits, STs, CBM Amiga, Unix(tm) boxes, etc.) are lumped together as "other". The totals for "other" are less than the totals for any of the top 4 markets.

There just isn't a lot of money to be made writing or converting program for the 8 bit systems. As long as the market is small you are going to see very few of the larger software publishers supporting the 8 bits. Small publishers or publisher/authors will support the Atari 8 bits since they can get by on smaller margins (no support staff, etc.).

I downloaded this file a couple times, and every time I got the same thing: a truncated file. The ARC file produced is ok except for the last file which also seems to be the main program. Could you fix this problem and let me know? Thanx.

It's good to know that someone still has an 8-bit! I have an 800 that still
has a CTIA in it! Too bad I can't find any good software for it anymore :-(.

Anyway, I'll just spoil it because the puzzle is SO stupid and I happened
upon it by accident.

You need to get across the 'chasm' so...

you melt the square rock, hold the green rock...

stand on the melted square rock, and (drum roll please)

push the josytick UP. Dumb.

It is possible to do all the planets without dying including the fountain
of youth. Consistently. Anyone want the trick? And it's a feature!

Has anyone heard anything about GEO lately?? There is only
one good sized computer store in the area that still gets atari
8-bit stuff, and they say they havn't heard anything about it...
I am interested in getting it, when ever it comes out.. Mostly
everything I've heard has been good (someone once said something
about 40 swaps to copy a disk.. can anyone confirm/deny this??).
I don't know how far this note will get- I've heard rumors that
bitnet isn't working well, and I havn't gotten any mail for a while..

Kit & Daryl, plus anyone else who'd like to comment:

What and how big a role does software piracy play in the development and distribution of Atari 8bit software? What software protection schemes are the current rage, and how does that affect the ability to successfully market (and make money off of) Atari software? I had heard that piracy was the prima primary reason new titles were not being developed for the Atari 8bit.

Thanks for your replies!

From: killer!netsys!c3pe!charles@ames.arc.nasa.gov (Charles Green)
Subject: Re: Serial Interface

In 1982 I wanted to build a serial port for my ATARI but didn't have much
money, so I investigated building one. Fortunately, I worked for a company
that had an agreement to build hardware for ATARI CORP. so I had a complete
(preliminary) copy of what became the Technical Reference Manual. I
designed and built the hardware, and software drivers, and terminal
emulator (complete with XMODEM file transfers) for a "mainly software"
serial port. It had 2 ports, hardware/software busy and baud rates of 0-9600
baud. (Due to the clock frequency of the ATARI, the margin of error at
19200 baud was a little too big). The hardware consisted of 3 chips and an
external power supply. Today it could be done with 2 chips and no external
supply using the MAX-232.

On of ATARI's best kept secrets was not so much the fact that the POKEY
chip had a serial port built in, but the fact that it was a full standard
ASYNC port! There were two problems: 1. The data was TTL not RS-232. 2.
When diskette (or other intelligent device) I/O was performed, the serial
port needed to be told not to listen.

Problem 1 was easy enough. As was stated earlier the voltage-level
translation is easily done with the MAX-232 chip. At the time however this
chip was not available, so I used the readily available 1488/1489
combination along with a -12v supply. The +12v was available from the SIO
connector, and I added the -12v with a $2.95 DC wall transformer (came from
an old calculator).

Problem 2 was a little more difficult. At first I tried using the cassette
motor control line and had no problem telling the serial port to listen. I
did have a problem telling the port to NOT listen. It seems that the motor
control line decayed too slowly after turning off. It was meant for a
device that drew more current than my tri-state buffer was using.

After a lot of thought, I decided there was no alternative, so I went ahead
and used one joystick port to give me the extra hand-shaking signals that I
needed. This also gave me enough signals to add a second serial port along
with hardware busy for both ports!

Well to make an even longer story a little shorter, I got it completely working, built a few prototypes, and had dreams of getting rich marketing it. (At the time the only game in town was the ATARI 850 at about $175). Needless to say, this didn't happen, and I still use one of my prototypes. I noticed several references to building an ATARI serial port including erroneous data, so I thought that if anyone is interested I will dig this all out of my archives and make it available.

If anyone is interested, I will make available the following:

1. Complete Hardware schematics.
2. Software driver including source for two serial
ports configured as P:, and R: (user changeable).
3. Terminal emulator capable of 110-9600 baud,
user selects type of busy i.e. Hardware/XON XOFF

Just send me a blank diskette and a SASE with enough postage to accomodate the bundle. Or, just send $5 and I will send it all to you. Or if you send me three blank disks and a SASE with postage I will include the source for the terminal emulator. Or send me $10 and I'll send you everything above with all the source. It shouldn't cost much more than about $15 in parts to build the hardware. (THE SOFTWARE AND SCHEMATIC ARE NOT PUBLIC DOMAIN THEY ARE ALL COPYRIGHT 1983 PAUL M. WALTERS)

I would like to find a VT100 emulator that works under SpartaDOS off hard disk, with a Hayes-compatible 1200b modem. I tried VT10*2 and i work only under Atari DOS 2.0 on a boot disk.

So far, I think my favorite of all time term package is 850 Express. I wish I could find an 80-col emulation mode of it. I don't suppose there is such a beastie?

Source record: 116227

Piracy is not the reason why new 8-bit titles haven't been released for the Atari 8-bit. The reason is because it is not worth as much to CONVERT games to the Atari 8-bit. Why should a game company use 3-6 months of it's programmers time to convert a game that will sell less copies than a new game for the C64 would sell?
We Atari 8-bitters have to face the fact that until we get a larger user base willing to shell out $40 per game everytime a new game comes out, we aren't going to get any new games (or applications for that matter).
I do not often buy "converted" games, they are usually horrendous conversions. The worst example I have seen (and bought) is the Superman game. It looks nice on the C64 but is missing 1/2 the game on the Atari 8-bit. The reason the programmers gave was because the Atari has less memory! (The game requires a 130xe/800xl.) I dunno, maybe my math is wrong but I have checked out the 64 versus the 800xl and the 64 has less usable memory. Of course, the best conversions are great, anyone ever play the Ultima series? The converter for those games is known as Chuckles and he does a great job!
This leads to a fact about software companies...they are out to make a fast buck...and they don't care about the quality of their games in secondary markets. Good examples of this are the Superman game above, OGRE (the ST/Amiga/IBM version allows you to play the OGRE versus the computer). These are simply done for economic reasons, but of course, whenever a game or application doesn't sell it is attributed to piracy. The software companies may believe that but I think it has a little more to do with price versus quality. As an example I wouldn't buy a $400 Lotus 123 spreadsheet when a $99 spreadsheet does everything Lotus does and more. It is easier for software companies to scream "PIRACY" than to believe that they may have put out an inferior product.
Comments from programmers/software companies welcome.

Well, Christmas time is here and I'm definitely in a game-playing
frame of mind. While taking care of all my frantic Christmas
shopping, I've been checking out the home video game scene...
and am a byte concerned. On the Atari front, I've seen plenty of
new carts for the 2600/7800 systems. BUt I have yet to see even
one new game for the XEGS - it's all the same stuff that been out
since the summer (ie - Gato, Barnyard Blaster, etc.). I know someone
posted a list of coming titles several months ago, and there were
more than a couple that I was interested in buying (Crossbow, Dark
Chambers, Desert Falcon to name a few - and by the way, those last
2 are currently on shelves for the 2600!!!). Anybody know what the
deal is? Have they dropped these games, or pushed back the release
date or what? I'd have thought Atari would have really pushed to
get some new stuff out for the holiday season of all times...

-Ray

As a member of a User Group and a supporter of some local BBS's, I have to say that the majority of currently active Atari 8bit users are extremely conscience of the piracy problem. NO pirated software is allowed or even discussed at our User Group meetings. This is not to say there are no pirates. I don't know if there are or not. However, I do know that there are local boards that have some pirated software on them and, frankly, I'm glad that they do. If it weren't for this "service", some of the older software would no longer be available. Even some of the newer software that has been available in other countries but is not available in the US is available this way. Two that I have seen are Amourote (sp?) and Arkanoid. Arkanoid is a GREAT game and should be available here. I would buy a copy, even though I already have a copy.

Honestly, I don't see piracy as the major problem. As has been stated before, the number of sales determine whether a company supports a certain computer or not. Commodore and IBM piracy is rampant, but they have such a large installed base and sell so much software that the companies put up with it because they still make a handsome profit. Atari software sales are way behind any other major brand computer. Even Infocom sees that it isn't profitable to convert their games for the Atari 8bit computers and they are mostly text adventures, with little worry about the graphics conversion problems. What's the answer? I don't know for sure, but Atari has to be in the forefront of the software battle. They have stated that they will be (at least, in cartridge based software), and that is a good commitment. I just haven't seen as much in the way of results as I would like. The XE game system is selling pretty good around here (thanks in part to Nintendo selling out again this year). Atari has to build on that momentum and strike while the 'iron is hot' but releasing good quality software. Kids are fickled. If their parents buy them an XE game system and they can't get 'Super Mario Brothers' and good software like their friends have, they will be back asking for a Nintendo for their birthday. I know my son has been after me for more than a year now, but I haven't caved in.

Source record: 116233

About a year and a half ago, I purchased an X10 controller interface.
It uses RS232 to comunicate to the outside world. I Was also working on
a joystick interface. It is simple hardware. It's just a joystick
cable with a resistor. The software was simple. I had the X10 to atari
working sorta ok, but the atari to X10 had bugs. I gave up and used
an 850 interface which supports rs232 already. As far as I know there
isn't any software written for the 8bits and the X10, and I have been too
busy with other things to ever get around to doing it. I do recal that
an (ANTIC/ANALOG?) issue had an article on the X10. You might try looking
there.

1780. XL/XE CONSOLE KEY FIX

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-20 04:51:30 UTC
From: curzon@troa01.dec.com
Message-ID: <8812200451.AA18358@decwrl.dec.com>
Source record: 116234

SUPPLIED BYT THE CHAOS BBS
(517) 371-1106

XE CONSOLE KEY FIX...
... that really works.

I found that I was not alone when I started having trouble getting my console keys to work on the ATARI 130XE the CHAOS club used for its BBS. It seems that very many of the machines develop this problem. I asked around and found several others that had done as I did, opened the keyboard and cleaned the button contacts, only to get good results for a week or so before losing them again.

I then received a couple reprints of articles suggesting hardware fixes. I tried a couple that did not work, but one that worked the best came from Alan Haskell (printed in the SBACE GAZETTE, April/May '86). Heres how, with a small modification to save you the trouble I made for myself trying his recommended installation.

You will need a small phillips head screwdriver, needle nose pliers, a small soldering iron, and three 3k (3,000 ohm) resistors.
Quarter-watt rating is plenty, in fact, the smaller the resistors are physically, the better.

1. Turn over the XE computer and remove the 4 screwss that hold it together. Turn the computer over again and remove the top half of the case.

2. Lift out the keyboard and gently pull the ribbon out of its

connector. DO NOT OPEN THE KEYBOARD as cleaning internally will not help, and you may damage the carbon tracks on the baking sheet inside.

3. Remove the motherboard from the lower half of the case by removing the phillips screws holding it down.

4. Remove the top and bottom metal sheilds from the board by carefully straghtening the bent tabs that go through the board.

5. Observe the top and underside of the connector you pulled the keyboard ribbon out of. As seen from the top as you would look at the computer normally, there are 24 connections, with connection #1 at te left and #24 at the right. Connection #3 (from the left) is the ground connection. The last 4, #21, #22, #23, #24 are the START, SELECT, OPTION, and RESET connections. When a connection is made from these points to the ground, the computer will know one or several of the keys are being pushed. Due to a design problem, the console keys have a bit too much resistance to always register even when you really lean on them. So, we will install the three resitors between the connections and ground so as to "leak" a bit more ground signal to the computer. That way, not nearly so good a connection is required by the actual keys when pressed.

6. Identify the proper pins on the bottom side of the circuit board. We will install the resitors under the board.

7. Solder one end of all three resitors together. Then connect this common end to the ground connection (pin 3). Then solder the free end of the resiters, one each,

to pins 21, 22, and 23. (The reset system never seems affected, nor any other keys.)

8. Be certain that the wires on the resistors do not touch each other nor any other circuitry! Use as little solder and as short a heating time as possible. Tape the resitors to prevent shorting if needed, and press them close to the circuitboard.

9. Reassemble the shields to the board, bending back the tabs to hold it all together. Look inside to be sure the resitors do not touch the lower shield.

10. Complete the re-assembly, taking extra care not to stress or insert the keyboard ribbon too many times. The spring contacts bend easily, and the conductive coating on the ribbon, if scratched through, will cause the keyboard to be useless. Don't worry too much, thats hard to do if you are careful. (The original mod suggested pressing the resistor leads into the connector so as to make it solder-free and simpler.... but that "simplicity" ruined my connector and made hour more work! Solder it!)

11. Test the repair. Power up the machine and type in this one line basic program:

```
10 PRINT PEEK(53279):GOTO 10
```

Then type RUN. You will see a row of 7's down your screen. Push OPTION. They should turn to 3's. SELECT will give you 5's, and starts will give you 6's. Combinations will give other numbers from) to 7. If each key responds, you have finished the repair.

This has permanently fixed the problem on dozens of XE's. It has restored my keys to "feather touch" after a long siege of having to boot 5 or 6 times mashing the OPTION key trying to get a boot without BASIC. It WILL work for you.

John Nagy, SYSOP of the CHAOS BBS
(517) 371-1106

I have written an Atari BASIC program to control the X10 Computer Interface.
I have designed it in such a way that it can be run over a modem. It is
kind of like a BBS that controls your house. The user can set the clock
in the interface, read the clock, send a direct command, and program a timer
event. The only thing I need to do yet is provide a command to read timer
events from the interface memory and display them to the user.
One of my friends has also written a controller program, but his has
a Mac-like user interface. The user controls a pointer with the joystick
and selects commands , but he did not have as many functions implemented.

If anyone is interested in either of these two programs, let me know. We
can probably work something out.

Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

I am not sure if this is the place to post this, but it is the closest catagories that I could find.

A couple of years ago, I bought an atari 5200 when it was the "best" game system that they put out at the time. They promptly discontinued the unit and came out with the 7800. At one time an adapter was made to run 2600 cartridges on the 5200, so I know it is possible to get new games (albeit lower quality graphics).

What I would like to know is that adapter still available (and will it work with 7800 cartridges) or better still what is the pinout for the edgecards of the cartridges for the 2600, 5200, and the 7800.

Is there any interest in addons for this game? Or am I the only one who hung on to one? Are there still suppliers of game cartridges for the 5200?

Please send replys to the address below as I do not normally read these news groups.

In yesterday's mail I finally recieved the info
I had requested from TCS (company making GOE)
This was a nice vague little flyer that after all
the hype made only one thing clear. That was that
the GOE cartridge only needed 8k to run a 64k
program. The only other thing that the announcement
had was that for persons who ordered this cartridge
and had the flyer the cost was $50.00 U. S. I don't
kow how much it was without the flyer. I'll wait
for a review to be posted here before I decide to buy
but for now I'll keep the flyer. Never know this could
be just what the 8 bits need :-)

1784. GEnie -- a CP/M resource

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-21 23:07:00 UTC
From: bridger%rcc@RAND.ORG
Message-ID: <KPETERSEN.12456396195.BABYL@WSMR-SIMTEL20.ARMY.MIL>
Source record: 116238

An excellent source of CP/M information, help, and user-group software (over 4500 files) is the National CP/M RoundTable on GEnie, which is accessible in the U.S., Canada, and Japan through the GEISCO network at 300 and 1200 bps.

The Bulletin Board area has several user groups to answer machine-specific questions for the TRS-80 using CP/M, Heath/Zenith, Kaypro, Osborne, Visual-1050, Commodore C128 using CP/M, Apple using CP/M, Atari using CP/M, and a category to discuss ZCPR3, ZRDOS, and the Z-SYSTEM.

A particular strength of the CP/M Roundtable is the depth of experience that the four SysOps bring to the system. Keith Petersen, surely known to everyone on this list, guides the overall CP/M activities. He is backed up by Bill Duerr (All CP/M), Bill Juliani (Commodore C128 CP/M), and Jim Lill (Apple CP/M and Z-System).

Since late October, the normal $29.95 signup fee for U.S. users has been waived (this waiver may be terminated soon, however). This means you can sample the system at very low cost. To get this free signup you do this:

1. Set your Terminal software for LOCAL ECHO/Half Duplex at 300 or 1200 baud.
2. Dial (toll free) 800-638-8369. Upon connection, enter HHH
3. At the U#= prompt, enter XJM11890,GENIE and press RETURN.

GEnie is available without monthly charge and without any hidden extra charges for $5 per hour for both 300 and 1200 baud. You will be able to order a GEnie manual online or download one from the online manual. If you need additional assistance, call 800-638-9636 (voice).

Additional information is available in these simtel20 files:

PD2:<CPM.GENIE>GENIECPM.FRE
PD2:<CPM.GENIE>GENIECPM.INF

1785. termcap/terminfo for Atari 800 XL wanted

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-22 21:12:38 UTC
From: tbetz@spies.UUCP
Message-ID: <298@spies.UUCP>
Source record: 116239
Cross-posted to: comp.terminals,comp.unix.xenix,comp.unix.questions,comp.sys.atari.8bit

I'm in the rather unusual position of wanting to use an Atari 800 XL
as an occasional terminal for vi on a SCO Xenix 2.3 system.

Can anyone provide termcap and/or terminfo for the Atari 800 using
the dummy terminal software in ROM in the 1030 modem?

I'd very much appreciate receipt of same.

Please cc: to e_e_cummings@philabs!citasim.UUCP as well as
tbetz@philabs!spies.UUCP, as spies may shut down for about a week
at any time in the next three, and I don't want to miss your mail.

Thanks!

Does anyone have an address (e-mail or paper mail) and/or phone number
for a company called "Innovative Concepts" (sounds vaguely familiar, but...)?

I have been told that they sell a color Koala (Microillustrator) picture
dump utility that fully supports the Star Micronics NX-1000 Rainbow (because
the Rainbow is "Epson JX80 compatible").

Thanks in advance!

An interesting point has been brought up... That of software no longer offered by any company commercially. What happens to these programs? Obviously, the copyright doesn't just vanish... Kit pointed out that some pirate boards do a "service" by keeping older out-of-orint titles alive. I am sure the copyright holder would have something to say about this. Is there anything we can do to get out-out-print software placed in the public domain, short of asking the author to tea? ;-)

January 1988 Computer SHopper contains an article on the politics and specificatins of the GOE and DIAMOND graphic operating systems soon to be released in cartridge form for the Atari. Pick one up at the newstand if you don't have a subscription! Good article, though the reviewer warns that until the carts are released and reviewed together (these being the only two real contenders) any review will be incomplete.

I found another listing. There is a company that someone mentioned here
in this newsgroup called Terrific Corp. Don't remember where they were
located, but the same day this message came in, I had picked up a copy
of the January '89 Antic.

Well they have restarted their 8 bit Catalog and one of the listings is
Terrific Corp.'s software for controlling X10 devices. Apparently it
supports a device called Powerhouse Interface from X10 and is called
PowerManager. Antic's code for this is TH0029 and is shown as $24.95 US.

I don't know more than that about this, since I am not affiliated with
Antic except as a reader of their magazine.

RCH@cup.portal.com

^^
All above written by RCH@cup.portal.com

That is exactly the problem Ric, Atari users want quality at a reasonable
price. The Superman game cost $10 and I feel I was ripped off for $7 of that
$10. About the game/program switch, sorry but that is the way it looks right
now. Atari 8-bits and Commodore 64/128's have been relegated to the status of
video game machines. I prefer applications but the best ones are appearing as
public domain or shareware which makes it even harder on software companies.
Imagine SpartaDos being public domain, and Atari Dos being sold; why in the
world would anyone BUY Atari Dos?
Some examples of high-quality programs in the 8bit world:
Express 850
DeTerm
MyDos
Super Arc/Unarc (Robert Puff)

I know others but I can't think of them off the top of my head.
If anyone has their own list of high-quality software, please post it.

Ordania-DM@cup.portal.com

1793. Re: Financial aspects of new 8 bit software

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-25 20:52:33 UTC
From: RCH@cup.portal.com
Message-ID: <12954@cup.portal.com>
Source record: 116247

Charles Hughes [Ordania-DM@cup.portal.com] listed a few programs that
are great code, and ShareWare, including 850 Express!, Super ARC/unARC, DeTerm
and a couple of others... These are programs written virtually for
free by the authors, and placed in the public domain in-so-far as they
require only credit via copyright, and no actual retail price.
It is (usually) very good code, better oft-times than the offerings
of Atari and its third-party software developers... A fact that early on
Atari tried to capitalize on (heavy relations with Users Groups)
and now seems to brush aside as trivial...

As a programmer who has written a few utilities, or mods to other programs,
please, do this as a New Year's Resolution:

Look through your software libraries for really good "Public Domain" or
ShareWare programs, and select a couple that are your favorite, or that
you use the most, and send the author $5 or $10. That will *not* set you
back much, and it could make the difference between whether we'll see any
new terminal programs like DeTerm [just dl'ed it a couple nights ago from
GEnie and *love it*, even more than 850 Express...] and Bob Puff's ARC
utilities.... I am not a big game player, though I am sure there are
not a small number of ShareWare games out... But please, if Atari and its
developers won't come out with new product, support those that do!

Merry Christmas, Happy Holidays, and make that resolution stick! I am!

I wrote this up long ago, when I was still using a 1030. Somehow
though, the thought of trying to use vi at 300 baud just isn't
very positive... Good luck.

1797. DLI etc

Newsgroup: comp.sys.atari.8bit
Date: 1988-12-27 19:08:58 UTC
From: slackey@bbn.com
Message-ID: <33887@bbn.COM>
Source record: 116251

I have finally done my first DLI <yawn> so what's the big deal?
Well - I first did the following. I changed the display stuff at
some point on the screen, to change the color registers and the character
set, and relied on the built in vertical blank routine to change them
back for the top half of the screen again. Well, it seems like
CRITIC gets set a lot more than I expected, as there was a lot of
flicker on the to half. So, I made an addition to the first stage
VBI to set the character set and colors back all the time.

I still get some flicker (it seems to miss either interrupt from time
to time, say once every 10 seconds)!

Is this a reality in the Atari, or did I not set something up right?

-Stan

1798. commodore mouse

Newsgroup: comp.sys.atari.8bit

From: slackey@bbn.com
Message-ID: <33889@bbn.COM>
Source record: 116252
Cross-posted to: comp.sys.atari.8bit,comp.sys.cbm

Well, I just *know* I'm going to alienate both groups, but I am going to say it anyway...

I am trying to use the Commodore mouse on my Atari.

The mouse runs in either of two modes: sleazy joystick mode, or proportional mode. I have gotton joystick mode to "work" as well as it can, but proportional mode would be much better.

The mouse docs say that the X/Y coords are sent on the pot lines.

Now - It seems that the way Commodore reads the pot lines is different from the way Atari does. Simply reading the pot registers as one would on the Commodore does not work on the Atari. Does the mouse send an analog voltage proportional to the distance the mouse has moved? Does anyone know?

I have directed followups to atari.8bit, or just reply. Thanks. -Stan

Yes a Programers Book comes with the unit. I got mine from DAK for the IBM machine. I have written a complete interface for the 8bit systems, and if someone can tell me a sure fire way to post it, I will. I have tried to get stuff from the net and unscramble it to my 8bit with very litle sucsess.

The software I have written does everything with the only limitation being it supports any 15 of the possible 256 addresses. I have never even got close to 15 different 'chanels' so this is no problem for me. I use the 850 with mine, but a friend has used the P:R: connection.

PS: I have found several mistakes in the programers book.

Source record: 116254

At least a couple guys here have mentioned that they bothered to write the software to control the thing.

PLEASE POST THIS SOFTWARE!

It's one of those programs that, as a programmer, I would have written, but with a Unix workstation sitting next to the XL, well, I, uh, didn't.

Also, PLEASE POST THE SOURCE!

Whereas figuring out ALL the mechanics would be a pain, as programmers yourselves, you most certainly know that it's a lot easier to edit than to punch something out from scratch. I've deleted 99% of a program in an edit, but psychologically, it's "just an edit."

When you get sick of working on your program any more ("Hey, it works") that's when you POST THE SOURCE, such that someone (like myself) can add whatever features he wants and then post it back.

Eventually, these things turn into really nice programs.

Just for the nets sake, there are a lot of people out there who can't get files from the net. If you want to make things acessible to everyone, please consider uploading them to the Club II (BBS) in Detroit. I do my best to keep everything that is posted on there, and there's plenty of space. We're going to add another 65 meg in the near future.

Thanks!

(P.S. I know, "Why the Club II?" 'Cause it's free, there are 8bit programmers on it, and when was the last time you saw a 100-meg board that actually kept 8bit files?)

From: charles@c3pe.UUCP
Message-ID: <6243@c3pe.UUCP>
Source record: 116309

I am attempting to write a simple oscilloscope program for my Atari 800XL, and have run into what appears to be a snag. Although I can appreciate that the accuracy of the reading may be reduced by a few significant bits, it appears instead that, depending on the pot value, *most* of the readings I get are completely bogus. I *think* I am doing all of the necessary steps in the correct order, as specified in Atari's Technical Reference Manual for the 800. Has this interface changed somehow for the XL series?

I will, of course, summarize any mailed responses. Thanks!

Go through DOS 2.5. There is a 2.5 utility to convert 3 -> 2.5. Since 2.5
is compatible with 2, that should do it.

Well, like you said, the VBI CRITIC flag is there for a reason. It is
needed for the OS I/O routines. Stealing the first stage VBI and doing some
hardware poking, then vectoring to the second stage is your best bet. Just
remember that during the horizontal blank (DLI), you only have enough time
to change one or two registers after the WSYNC.

The _Big Deal_ about DLI's is what you can do with them. Sure, everyone
today can change the colors of the screen midway down and change the
character set pointer. But the DLI is more than that. I have used the DLI
in the past to simulate a 3-D scrolling maze, where the VBI created a custom
DLI each time the player moved.

I also have created a "virtual sprite" system with the use of the DLI which
allows many, many more sprites than the 4 hardware limit.

Just some food for thought.

I have an 800XL that seems to have a heat problem. When the system is on for an hour an a half the screen starts giving me multiple characters flashing randomly. Has anyone else seen this kind of problem ? Could it be the RAM chips ? The RAM in my system are NEC D4164C-15 and -3. I can replace them if I knew what to replace them with, any ideas ?
Thanks for any help.

Ken,

Are you sure the problem is in the computer? I had a similiar
problem with one of my 800XL's a while back, and the solution was to get
a new power supply. Now it works fine, and I never had to open the
computer (although it's been opened for other things... :))

(I haven't yet figured out how to get Portal to 'include' text of previous postings... sigh...)

I once found myself needing to transfer files from DOS 3 format to DOS 2 format, but without access to DOS 2.5 or any other "transfer utility" program. I was able to solve the problem by running a BASIC program that started out running under DOS 3, read data from the "original" file into a buffer string, then somehow (I have unfortunately forgotten the details but you might be able to re-engineer it) warm-rebooted into DOS 2 without losing the data, then opened a file (now under DOS 2) and wrote the data back out. From the program's point of view, it "transparently" READ one file, and WROTE another, using DOS-version-independent OPEN, GET, and PUT statements -- but with the alteration, in the middle, of the underlying DOS support, it wound up transferring data from one format to the other. (It is worth noting that transfers in the OTHER direction did NOT work when I tried them; apparently DOS 3 boots up differently from DOS 2, or its memory requirements are different, with the result that the technique I used (I believe it was a USR call into the bootup code of the OS) works ONLY in ONE direction, and not in the other. This means that you have to reboot anew into DOS 3 for each file you transfer. Also, if the file to be transferred is larger than the buffer memory size, you have to transfer the file in several pieces (transfer the first N bytes; then reboot, alter the program to SKIP the first N bytes of the file and transfer the NEXT N bytes..) and then re-APPEND them under DOS 2 when you get them there.

All in all, it's probably EASIER for you to find an existing utility, but if that pans out, this is one way to do the job with what you already have.

I've seen exactly what you describe (provided you have an accurate
description, of course). I'd be willing to bet it's the 800xl power
supply, since that is what failed in my old system. They are hard
to come by in the Sacramento, CA area, but they may be easier where
you live (BTW, the 130Xe and 800XL power supplies are identical in
output).

Message-ID: <13306@cup.portal.com>
Source record: 116318

In reference to the question on the 800XL heating up and flashing random characters on the screen... I own an old 800 that no one can figure out what is wrong with. I had it serviced by American Technavision (not a good experience) and they replaced all the RAM chips and claimed to have it in tip-top shape. It had been struck by lightning.

Well, the RAM cards had all jarred loose in shipping, so I plugged them back in (remember that the 800 has multiple boards... XLs and XEs are all on one board). It seemed to work fine, but after it had warmed up (say, about 15-20 minutes) the screen started displaying horizontal rows of seemingly random characters, then switched graphics modes, and finally went black all together. After letting the 800 cool off, I turned it back on. It worked fine for 10 minutes, then the same thing happened.

Our best guess was that a power transistor was going bad, or that some screen RAM was bad. We had it checked and reserviced... They couldn't find anything wrong. Then I had an idea.

I asked them what sort of power supply they were using. They said they had a special bench power supply that they used to test all equipment. I was unable to get any specs on it. The 800 uses the same power supply that the 1050s and 810s (disk drives) use, with power rating given as 31 VA. I was thinking that possibly the overheating power transistor was drawing more current than the power supply was
rated at, and that the special power supply used at the service place was capable of delivering more amperage. But I have been unable to determine exactly how much current it would take, or to find a power supply that was rated at higher than 31 VA (34, maybe? It is a weird rating, according to a local electronic supply house.)

If you find anything out, and if indeed this is the same problem you are havin having, let me know what happens via mail.

1815. a few questions...

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-08 20:52:00 UTC
From: BIW109@URIMVS.BITNET
Message-ID: <8901082054.AA22903@ucbvax.Berkeley.EDU>
Source record: 116319

Now that Bitnet has stopped sending me error messages, I have a few questions... 1) Dos anyone out there have a schematic of the 1200XL computer?? I would be very interested in getting a copy of one.. 2) After seeing a friends okimate-20 printer, I began to wonder if it is the same as the okimate-10, only white instead of black. The interface and printhead connectors have the same number of pins, and appear to be compatable. The only difference is that the 24 element printhead of the okimate-20 has a "glue chip" (an integrated circuit covered in some kind of black sealant). The reason I asked is it would be cheaper to simply buy the atari interface and a new print head and plug them into my okimate-10. Any ideas on what might happen?? We plan on tring an experiment to see if the printer itself is compatable by putting the commodore interface and 24 element printhead in my okimate-10 and tring it on his computer (or putting my interface in his printer and using it on the atari, either way). Of, course, I will check some things first, such as the power supply to the interface card... The last thing I want to have happen is to quote Bill Cosbey's dentist routine-- "smoke, smoke, smoke.... Fire!!" I have been wanting better print quality for a while, and if this works it could be a cheap way to get it (assuming I can find the atari version of the plug-n-print card...).

Source record: 116320

Hello all,

I just recently downloaded kermit65 from the 8-bit archives on score, and
I have been having problems with it. I am using it from spartados 3.2 on
an unmodified 800xl. Here is my problem: I would like to upload a file,
so I go into ckermit on a vax runing vms 5.0. I type receive at the ckermit
prompt and the hit option and type send file.ext. It transfers the entire
file, until it gets to the last kermit block. Then it locks up. So I hit
reset and reloaded kermit65 and connected. I was still connected to the host
and still in ckermit receive. I got out of ckermit by hitting cntrl-y
and found that the file I uploaded was all there intact. Great, I can upload
but I have to reboot to finish the upload???? Any clues??

Jim Otto....

P.S. Please reply to me as I dont read the newsgroup often..

1817. Heat Problem

I doubt you will be able to use the 1351 mouse's proportional mode- it takes advantage of special features built into the C64/C128 computers.

The mouse uses the SID (the audio chip) POT registers to pass digital position information from the mouse directly into the C64/C128 memory map without processor intervention.

The SID A/D conversion cycle is 512 CPU cycles long. During the first 256 clocks, SID sinks both POT lines, discharging some small caps in the computer. During the next 256 cycles, SID starts an 8-bit counter and releases the POT lines, allowing them to charge at a rate determined by the mouse. When the voltage at the POT input crosses a threshold the counter value is latched into the appropriate SID POT register. The conversions are automatic, and cannot be affected by the processor. Tricky, eh?

It is only necessary to poll the mouse at a 60Hz rate to accurately determine its position. If you buy a 1351 mouse, a diskette is included with 6502 source code and demo programs.

According to a transcript of a conference I read (or an article, I'm not entirely sure which of umpteen places I read this), the older XL power supplies were not rated (in terms of current) as high as the newer ones and XE power supp. This apparently caused some supply burn-out problems for people with memory-upgraded XL/XEs who also had P:R: Connection devices (which draw power from the %V SIO line), etc. The upshot was that the newer power supplies put out enough current to cure the problems. (1.5A vs. 1A ratings as I recall...)

Fred Bowen writes about how the C-64 reads the 1351 Commodore mouse..

Fred, if you're still tuned in here, is this A/D process similar to the way the C-64 reads the Paddle pots..?

The 8-bit Atari uses a somewhat similar way of reading the A/D ports through hardware, although the scaling seems to be a little different. The Atari paddles on a C-64 give a slightly different range than the Commodore paddles do... also, a much asked question revolves around the differences between the Atari and Commodore versions of the Koalapad touch tablet...

I guess this is mostly out of curiosity, not any immediate application..

As far as the proportional mode of the 1351 mouse, does the resultant data get stored in the same locations as the paddle values..? If so, it just might be possible that the mouse could be read on an 8-bit Atari...
p t 0
I guess I'm just a little bit confused as to the actual input method from the mouse... if it's a variable resistance, as in a paddle, does the computer translate the x-y values into an absolute position, rather than relative direction and speed values, as an Amiga or Atari ST mouse..?

Again, just mostly curiosity, I guess...

>get stored in the same locations as the paddle values..? If so, it just might
>be possible that the mouse could be read on an 8-bit Atari...

I started this - I got a cbm mouse to use with the Atari.
The first problem was that it didn't even plug in due to differing mechanics
(on my XE - I know nothing of 400/800 or XL), so I had to go to Radio Shack
and get connectors. Their joystick extension cable might work - I didn't
think of it at the time.

The mouse runs in two modes: joystick simulator and analog proportional.
I use joystick simulator - the mouse puts out a 20ms pulse on the appropriate
lines when moved. I have an assem language routine that I invoke with a timer
that polls the lines, and updates memory locations accordingly. Like the
ST mouse/trakball routine I posted sometime back.

The reason I am going to all this trouble is for that second mouse button -
my religion does not accept one-button mouses. Also, I got the cbm mouse for
$40, and I don't even know how to get an ST mouse. And my trakball is
beginning to stick.

In joystick mode, the second
button can actually be read through the pot input; when pushed, it reads like
3, and when released, it reads like 230? or so.

Anyway, it looked to me like the Commodore and the Atari read the pot lines
in a similar way; but trust me, it doesn't work. In proportional mode,
the Atari pot registers read 230? or whatever the max value is, regardless
of mouse position.

I would love to get a curcuit to allow the Atari to read the analog output.
Joystick mode [insert obscene expression], but I can live with it for now...
-Stan

I have avoided jumping into the discussion because I'm not well versed on
the internals of the 8bit Atari, but I do know that it has to be possible.

Both Total Control Systems' GOE and USA Media's Diamond GOE are designed
to be used with an ST mouse. I have the TCS demo disk and it works quite
nicely with the mouse. I realize that this doesn't help you solve the
problem of HOW it works, but it is possible.

BTW, USA Media (formerly Merrill Ward and Associates) was/is selling an
ST mouse with their GOE system for an additional $39.99. I have seen
them for approximately the same price mail order from companies that
specialize in Atari hardware and software.

>I guess I'm just a little bit confused as to the actual input method from
>the mouse... if it's a variable resistance, as in a paddle, does the computer
>translate the x-y values into an absolute position, rather than relative
>direction and speed values, as an Amiga or Atari ST mouse..?

The POT lines are read on the C64/128 via the SID POTx,y registers, just as the 1351 mouse movements are. The difference between an actual paddle and the mouse inputs is how they are driven- the mouse manipulates the resistance (normally variable as in the paddle) such that the value one would read from the SID POT register is equivalent to the digital data corresponding to the mouse's relative movement (bits 6-1). The mouse's speed can only be inferred, taking into account the polling frequency and the relative change in position. The left button appears as a joystick "fire" signal, and the right button as a joystick "up" signal.

The specifics pertaining to the SID and the values of the caps and resistors (accounts for the difference between CBM and Atari scaling factors) can be found in the C64 or C128 Programmer's Ref Guide. The specifics pertaining to the value read from the SID POT register can be found in the 1351 User's Guide.

One important note- on the C64/128, a 4066 analog switch is used to toggle the POT lines between the two joy/paddle ports. The selection is made via one of the lines shared with the keyboard scan lines. This means a keyscan will temporarily clobber anything in the POT registers. Since the POT register requires some time to "charge" before its data is valid, at least 1.6ms must transpire after this switch has been twiddled.

1833. Atari 800XL manuals needed

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-13 23:27:13 UTC
From: davise@byuvax.bitnet
Message-ID: <315davise@byuvax.bitnet>
Source record: 116337

I'm not an Atari person, but my brother just purchased a little 800XL
but doesn't have a DOS,Owners, or for that matter, any other manuals.

Knowing how these old manuals go, does anyone out there have old used
abused, yet useful manuals going inexpensively????

I would appreciate any help, suggestions and helpful hints to the system. He's
getting tired of playing the games.

Please reply e-mail.

Thanks in advance,

Evan Davis

I would, as I don't have any other reliable way (short of dialing up Paybax
BBS or whatever long distance, which I'm not desperate enough to do) to get
Zmag. It is supposed to be on DELPHI but Kovacs (who is on there) rarely puts
them up. (I suppose I could nag him about it again...)

If a mailing list ends up started again, I would be willing to "trade" Chicago
Zmag/a\zine's for Kovacs' Zmags. (I sent Gary one, and could send more but
if he has machine space problems, well....)

1836. SXmodem amd Kermit 65

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-14 03:19:52 UTC
From: scott@cs.odu.edu
Message-ID: <7152@xanth.cs.odu.edu>
Source record: 116340

There is a version of Kermit65 for the sxmodem, right?
Does it work?

I do not have a sxmodem but in my general area a few people who have a
sxmodem have tried kermit 65 and have NOT gotten it to work.

I FTPed it from stanford... MY rverter and 850 version worked...
the sx version didnt.

These people have also downloaded kermit 65 from Genie and this ALSO
doesnt work.. that leads me to believe it is THEIR problem.

typical setup:
sxmodem
kermit65
SPARTADOS 3.2
atari 130xe

Could sparta be the cause of all this?

PLEASE SEND ME MAIL DIRECTLY.... I DO NOT READ THIS NEWS GROUP ALL THAT OFTEN!

thank you.

Message-ID: <40dda81c.142c4@retina.engin.umich.edu>
Source record: 116344

I've used kermit implementations painlessly on my 800xl, macs,
pcs, Unix workstations, and IBM mainframes, but I can't get
Kermit65 to talk kermit (specifically, to a Sun-3 under SunOS 3.4).
I tell kermit65

> send "d:hmwk5"

and it does a disk access and then silently returns its prompt.
I tell it simply

> send

and it claims to be sending out packets (containing god knows what), but it
can't get the other kermit to recognize them, no matter whether the
other kermit is in server mode

kermit -x

or simply receive mode

kermit -r

. What's the deal?

Are you sure the problem is in the computer? I had a similiar problem with one of my 800XL's a while back, and the solution was to get a new power supply. Now it works fine, and I never had to open the computer (although it's been opened for other things... :))

I had a similar experience. My girlfriend's 800XL was acting very peculiar; screen changing brightness, random funny characters displayed, wedging up for no apparent reason. It turned out to be the poser supply connector, it the little DIN plug that plugs into the back panel of the machine. Replacing the plug solved the problem.

I didn't find the ZMAGs posted a few months ago to be particularly interesting, but if other people like it then I won't be upset to see it posted again. It would be a lot better if the 8-bit and ST portions of ZMAG were *not* crossposted. I suspect that a majority of Atari owners are only interested in one model or the other, not both.

1845. Power Supply Heat Problem

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-16 12:18:50 UTC
From: tremblay@cg-atla.UUCP
Message-ID: <6448@cg-atla.UUCP>
Source record: 116349

To all those that suggested my power supply could be causing the random characters after two hours of use, you were right. I tried a supply from a 130XE with my 800XL and after 21 hours of continuous running the screen is in fine condition. Not even a hint of trouble. Now the problem is after 7 hours of my supply in the 130XE the only sign of trouble is the screen suddenly changes color while in use. If I hit the space bar twice the screen returns to a normal using state. So far no random characters in the 130XE. Thru mail order I can buy a new supply for $25.

Thanks to all those that helped me with this problem.

The system administrator here at pnet51 (People-Net node 51, Minneapolis) has offered to bounce Z-Mag/ST Report to a mailing list. This would avoid the problems that would come from dumping the magazine into a discussion newsgroup such as comp.sys.atari.st.

First, I need to hear from someone who can mail it here. After that's set up, "subscriptions" can be taken.

Incidentally, pnet51 is PC-Pursuitable (612-929-6699). I also can put the files in my directory, which is publicly accessible.

In reply to the one no vote, which I didn't see until after I posted my earlier article...
I never saw that discussion and I have been reading this newsgroup for 6 months now. So far the requests for the ZMAG posting have been all favorable except yours. There seems to be no reason not to post ZMAG that I can see; as has been said before and will be again...just use whatever feature you have available to SKIP the ZMAG posting. Since you are with some ST organization (I saw it in your signature) I suspect you are against posting of the ST mag. On that issue we agree...I'd much prefer the ST just died and we could get on with the development of a REAL computer! :) Such as the Atari 8/16 bit line. :)

Views and opinions change with time; since yours is the only view opposing the posting, I think it fair that we go with the majority and start posting the ZMAG.

(off the soapbox..only cuz it slipped out from beneath me)

New 8bit games: Crystal Castles 3 stars (out of four) - great for kids,
my 4 year old is completely mesmerized at the moment.

Into the Eagle's Nest - it is a similar scenario to Gauntlet, but a WWII
setting. However the graphics are ABSOLUTELY AWESOME and play is FASTER
than Gauntlet. For an 8-bit game this baby's VERY IMPRESSIVE. A MUST
have for all 8bit gamers. 4 out of 4 stars!

>Post ST report and STZmag to comp.sys.atari.st, Zmag to comp.sys.atari.8bit!

Posting ST Report and Zmag and STZmag to the net was rejected earlier, it seems, because they include advertising. If someone would take over the mailing list, then you could still receive the mags for free over the net. I sent mail to the old distributor (gary?) volunteering to take over the list; I received no answer. If someone could obtain the mags each week and mail them to me, I could restart the list.

1860. Newsletters (Was: The ZMAG/ST Report Mailing List)

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-19 14:05:54 UTC
From: ljdickey@water.waterloo.edu
Message-ID: <2030@water.waterloo.edu>
Source record: 116164
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st,news.groups

Background
In several articles, folks have said that they would like to have certain newsletters distributed to the net; "ZMAG" and "ST Report" have been mentioned. But support has not been unanimous; some say that such postings would clog their favorite newsgroup.

Some of those who favor net postings of newsletters, have asked whether they should be posted to one group or the other of "comp.sys.atari.8bit" and "comp.sys.atari.st" or to both.

There is another newsletter that has just come to my attention, called "lustletter", and it comes from just down the road from me, from the group "London Users of the ST". One issue has been posted, and the posters ask if we want more.

Our local systems here in Waterloo carry four news groups relating to Atari products,

comp.sources.atari.st
comp.sys.atari.8bit
comp.sys.atari.st
comp.binaries.atari.st

but there might be more.

Proposal
Now is the time to form a separate group for the posting of related newsletters. Those who want to recieve them may subscribe to that group. Those who do not, would not subscribe. This suggestion solves the problem of whether newsletters should be posted to the 8bit group or the ST group.

Now comes another question. If the existence of such a new group is accepted, what should it be called? I suggest that the name

comp.sys.atari.newsletters

be considered. There is a proceedure for forming new groups, and if there is support for the idea, we could have a vote to determine whether or not the new group be started.

Any comments?

> problem with one of my 800XL's a while back, and the solution was to get
> a new power supply. Now it works fine, and I never had to open the
> computer (although it's been opened for other things... :))

There is another problem that will do this sometimes. For
some reason Atari forgot how to solder for awhile (wave broke or
something). Some machines have the most atrocious soldering ever and
this will sometimes break free and make a real mess. It will often
masqurade as a thermal intermitent problem

If changing P-supplies fails to solve the problem then check
the solder joints at the power socket, then on the ram chips
(specially if you have an upgrade) then the processors...

Be seeing you

> Ordania-DM@cup.portal.com

Let me reiterate the arguments against posting the magazine to a newsgroup:

* It's not in character. Newsgroups promote group discussion. The Zmags are
not discussion; the Zmag editors and contributors are not even on the net.

* It's a commercial enterprise that carries advertising, which conflicts with
the noncommercial, cooperative nature of the network.

* It's excessively long. Some of us run UUCP nodes on SMALL systems -- I run
mine on two floppies -- and some of us have rather tenuous network
connections. Obviously that isn't a problem for those of you on Portal (a
commercial system), but Usenet consists of five to ten thousand sites with
widely varying capabilities.

* There really isn't very much interest in it. I posted an offer a few days
ago to set up a mailing list for e-mail distribution of the Zmag. So far I
have received exactly ONE reply. (The offer still stands.)

UUCP: {rosevax, crash}!orbit!pnet51!steve
ARPA: crash!orbit!pnet51!steve@nosc.mil
INET: steve@pnet51.cts.com

A suggestion:

Two moderated groups, comp.sys.atari.st.mag and comp.sys.atari.8bit.mag,
(or a single group, comp.sys.atari.mag) could be created, and all "magazine"
postings would go into these/this group(s).

The debate over commercial content in these magazines aside, this would
separate the magazines so that they could be archived separately and sites
that do not want to carry these magazines could so choose without disrupting
the normal comp.sys.atari.st and comp.sys.atari.8bit traffic.

Note:
I am not volunteering to run the debate or votes on this idea, nor to
moderate any group created.

we people of the lustletter argrre full well that there should be a separate
base for this, as then those that want the newsletters can get them. a separate
base will probably aslo encourage uploads as they will be easy to find...

1867. Re: Heat problem ???

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-21 00:20:51 UTC
From: Chris_F_Chiesa@cup.portal.com
Message-ID: <13760@cup.portal.com>
Source record: 116171

Hm, since we're all discussing heat-related problems...

My 800 began experiencing problems several years ago that gradually got worse and worse. First, most things ran fine EXCEPT AtariWriter -- THAT would run fine MOST of the time, but would OCCASIONALLY go crazy, scrolling the LEFT HALF ONLY of the editing screen (or, sometimes, popping up one or another of the menu screens, and scrolling half of THAT) when any key was hit. The problem was originally confined to occurring only at the main menu or in the editing window, and only happened about 10% of the time. A friend with an 800XL experienced NO trouble running the SAME AtariWriter entity (i.e., MINE in HIS machine worked fine). Over the next few years the problem gradually got worse, until last summer when the temps were 100+ degrees, when I found nearly EVERY program going visually insane after a certain time of continuous machine operation. Finally, even a short (2-sector!) graphics demo of my own writing, would randomly bomb out, eliminating my early worry that maybe something was wrong with the other, larger software packages I had...

I took it to a service place that handled Ataris, but (gee, this sounds familiar) they couldn't find anything wrong with it. Of course, they were looking at it in an air-conditioned shop, whereas the problem occurred in my un-AC'd apartment...

My solution? I bought a used 800 XL from a friend, and mothballed the 800 against future hopes of diagnosis.

And my only gripe: found out several MONTHS later, that the service place had neglected to re-install the five screws in the underside of the 800, that hold the case together... went back, they were nice about giving me screws, but those turned out to be the WRONG ONES. This all happened right before I moved 600 mi. away, so I'm still short on those screws... sigh...

Good luck to y'all with YOUR problems.

1868. Re: SXmodem amd Kermit 65

Good news! I have personally used Kermit65 with the SX212 modem connected in "direct SIO port" mode, if that's what you're asking about... I don't know the name of the particular handler I use, but the filename I've known it by is "RVERT212.BIN". You need to use the version of Kermit65 that does NOT contain the prepended "standard Atari R: handler," then either load RVERT212.BIN first and THEN load Kermit65, OR copy RVERT212 and then copy/append Kermit65 onto it to get a load-and-go SX212-direct-connect version.

I have it around here somewhere, if you can't find it out there in an archive, let me know and I'll mail it OR post if there is enough interest. I've posted Kermit65 and all of the handlers I have (standard R: device, SmartT: for XM301 etc., and RVERT212) several times in the past, but it seems there are new people looking for it all the time. Gee, I wish I'd been the one to port it, I could be making a business of this... hehe...

Pshaw. It takes but a single keystroke to skip a large article. If these newsletters are any good, the informational value will outweigh the dreadful inconvenience.

I say just post them.

Followups to news.groups, unless you're Richard Sexton in which case followups to /dev/null.

```
ANNOUNCING: THE BITNET ARCHIVES FOR 8-BIT ATARI SOFTWARE !
-----------------------------------------------------------

(I) Who can use the archives?
-------------------------

Anyone, on any network that can send mail to BITNET.

(II) Who shouldn't use the BITNET archives?
-------------------------------------

Anyone with FTP access to the Internet archives. This is to reduce
the load on the BITNET server. Besides, the path from the server to
the main gateways is rather long and seems to be rather failure-prone.

(III) How to get a list of available files:
-----------------------------------

To get a list of available files, send the command INDEX ATARI8-F
to LISTSERV@TCSVM.BITNET . BITNET users can send this via interactive
message; anyone can send it as the first line in the body of a mail
message.

The server will send you the list of files. Please be patient, and
don't send multiple requests if it seems to be taking too long. You
will get confirmation of your request before the list is sent.

There are, at present, many more files on the list than are actually
on the server. You can tell if a file exists by the last column
of information before the file description. If the column contains
a date and time, the file exists. If it contains a row of periods
(........ ........), the file has not yet been stored.

(IV) How to obtain files:
--------------------

Use the command GET to get files from the server. If you want,
for example, a file called K65EXEC UUE, the command to send would
be GET K65EXEC UUE . Remember that there are no periods between the
filename and filetype. Again, you can send the command by mail, or
(if you're on BITNET) by interactive message.

(V) Miscellaneous information:
-------------------------

(i) You should read the header of the file index. It contains
more information than I've included here.
```

(ii) I will probably not be able to continue as the BITNET archive
maintainer. I don't know at present whether John Dunning is
going to take over, or if he'll want to find someone else.
Until we hear further, contact him if you wish to volunteer.

(iii) If you have any questions, contact me at this address, though
I won't be checking mail daily any more.

This address may disappear. If that happens, try
SHAFFERJ@AMETHYST.BUCKNELL.EDU

Subject: Re: kermitting with Kermit 65....

No, it's not a filename problem; even when I try to get kermit65
to receive, and I can see the sending (remote) kermit's packets
on the RECEIVE DETECT l.e.d. of my modem, it still doesn't work.
I'm convinced I'm doing something wrong in the sequence of
commands to kermit65, but even with my MS in computer science
I can't figure out what. My gut feeling, however, is that
when I OPTION to Break the connection (the only way to get
the kermit65 command prompt), I've preveneted kermit65 from
talking to the other kermit. But the only way I know to
re-establish the connection is to interrupt the kermit65
kermit operation. Could someone post a complete sequencing
of the keystrokes used to do a send (or a receive) with
kermit65? Thanks for your patience.

1877. DLI's and other hardware

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-23 18:56:14 UTC
From: slackey@bbn.com
Message-ID: <34962@bbn.COM>
Source record: 116181

A short time ago, I posted that I was having trouble with DLI's; when I changed the color regs and character set in a DLI routine, and depended on the system VBI to restore them from the soft copy, I got significant flicker, both above and below the line I was using the DLI on. I then implemented a fast VBI routine that always restored the color regs and the char pointer, but still got occasional flicker.

The thing I neglected to mention was what turned out to be the problem: I was using a timer interrupt to track a trakball/mouse input. The timer interrupt frequency was quite high, interrupting several times per display interval. (I originally tried to use the VBI to track the trakball, but found that it was much too slow. Even moderate speed in moving the ball would cause it to overrun.)

I am now using the Commodore mouse, in joystick-simulation mode. It can be tracked at VBI speeds, not very well, but it does eliminate the above problem. I even eliminated the fast VBI routine, as it was no longer needed to reduce flicker.

Has anyone had this problem? Does it occur when the timers are used as sound generators? Is there a way around the problem [of fast timer interrupts interacting with VBI/DLI's]?

Oh - I made a mistake in a previous posting. My statement that using the cbm mouse in analog proportional mode read on the Atari as the highest pot value was wrong - it actually reads as the number 3 [where the range is 0-228], regardless of mouse position.
-Stan

>(I originally tried to use the VBI to track the trakball, but found that it
>was much too slow. Even moderate speed in moving the ball would cause it
>to overrun.)

In my old days I wrote a handler to keep up with a mouse as an input device
and I had the same problems at first. The VBI can not keep up with such a
device. My solution was to track it during the VBI and selected DLI's.

I think I did it every four or so lines and then also during the VBI and
got a very acceptable responce. You might want to try that.

Also, when working with DLI's, it is always good to split them over the
vertical length of the screen and handle them in slices. Since there is
very little time during the DLI, (I think it was about 14 color-clocks for
horizontal blank) splitting up the tasks into small chunks helps eminiate
flickering.

Remember that there is only one DLI vector, so it has to be reloaded after
each DLI slice.

1879. Re: The ZMAG/ST Report Mailing List

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-23 22:00:33 UTC
From: preston@felix.UUCP
Message-ID: <80492@felix.UUCP>
Source record: 116183
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

From article <511@orbit.UUCP>, by steve@pnet51.cts.com (Steve Yelvington):

[...writes about why "ZMAG" isn't really appropriate material to be posted to Usenet...]

I also would rather NOT see "ZMAG" posted here.

I read the issues posted and saw nothing of interest that I hadn't already seen elsewhere.

I would suggest that "ZMAG" be distributed by mailing list (or some other mechanism) because of the large posting size, the limited interest, and the advertising.

(Just my 2 cents :-)

1881. Need terminal program.

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-24 03:10:12 UTC
From: meadb@tramp.Colorado.EDU
Message-ID: <6056@boulder.Colorado.EDU>
Source record: 116185

I am in need of a terminal program with the following features:
-Can send a short break. (or transmit a ASCII character 29)
-Can emulate a vt100, vt102, or vt52.
-Has file transfer protocols. (ASCII send/capture, and (preferably)
Kermit, and/or (alternately) x, y, and/or z modem.)
-Should be public domain or shareware. (I don't want to spend
alot of money to find one that works.)
-Needs to communicate at 9600 BAUD.
-Must have an ASCII translation option.

Leave me email about any programs that qualify, Please include where I can find
it/them. If there are enough requests for it I'll sumerize to the net.

Thanks in Advance.

1882. Atari-8 archives

In article <511@orbit.UUCP> steve@pnet51.cts.com (Steve Yelvington) writes:
>Let me reiterate the arguments against posting the magazine to a newsgroup:

>* It's not in character. ..
>* It's a commercial enterprise that carries advertising, ...
>* It's excessively long. ...
>* There really isn't very much interest in it. ...

and he expands on these four ideas. However, there is an answer
to each of these comments and I will give the short version
of each. In separate posting, I proposed the creation of a new
group "comp.sys.atari.newsletter", specifically for things like
ZMag, ST Rpt, Lustletter, and if we are lucky, others.

(1) Things can and do change
(2) So what? I know that commercials have been on the net for
years; a few blatent, many subtle.
(3) No one is forced to subscribe to the newsletter group.
(4) The evidence Steve gives is flawed by the fact that most believe
there is a better way. Perhaps if they are forced into a corner,
they will take up his offer to run a mailing list.

1884. ZMAG Mailing List revived

Newsgroup: comp.sys.atari.8bit
Date: 1989-01-24 17:39:24 UTC
From: gl8f@bessel.acc.Virginia.EDU
Message-ID: <1040@hudson.acc.virginia.edu>
Source record: 116188

With help from Buzz Hamilton, I am restarting the ZMAG mailing list.
Actually, since I'm an ST user, I'd like to give this mailing list
away and handle just the ST mags, but for now I'll handle both.

If you want to be on the list (I don't have the old one), please send
me mail to gl8f@virginia.edu giving a return address. Please mention
which magazine(s) you want to receive: ST-Report, ST ZMAG, or ZMAG.

If more than one person at a site want to receive the same mags, please
get together and request only one copy. Also, if you have several possible
addresses (Internet, UUCP, Bitnet) please list them all so I can level
the load better.

I don't read this group, so send mail if you want to make comments.

Starting a newsgroup especially for a commercial enterprise would
be a bad idea. I for one will not accept or forward articles to
such groups. That's not what Usenet is all about and I doubt
whether very many Sysadmins are going to pay for somebody elses
commercial project. It doesn't belong here - take it someplace else.

Well, this list will not be idle if *I* can help it! We here at the University of Akron just got permission to use Bitnet, and this is the first list I looked at. I've had an Atari 800 (the old, beige kind) since the days when they cost over $1000, and I'll keep it for at least that much longer.
I can't remember the name of the person who posted the message that mentioned a PD VT-100 emulator for use with the SX-212, but whoever you are *please* tell me how to get my hands on a copy of it! I've been looking for such a thing for years, so I don't have to drive to the college all the time to get my work done. Is it the VT-100 program that gets a (small) mention in Antic's Catalog?

The 65816 is not yet available to the general public, but will be 'soon' according to Feburary's Computer Shopper. It is now available to beta testers and software developers. I've heard that it will sold with a totally rewritten, fully debugged, and fully compatible Operating system with a totally rewritten (and fast) math/floating point package, a compilable basic, and (perhaps) a full K&R implementation of C. An informative, if not overly enthusiastic review appears in the Nov 88 issue of Computer Shopper. As a long time Atari user, I view this with guarded optimism; I'll get excited when I see it actually up, runing, AND supported... If you desire any more information I'll dig up the articles over the weekend.

The following is a message from Dennis Beach at Purdue.. He does not have authorization to post to the net, so I am relaying this for him:

For a long time I have been wanting to experiment with the parallel port in the back of my 800XL. However, I can't find any info whatsoever about it. I have the XL supplements to the tech notes, but it doesn't even mention the port. I would like to know what locations control the port, and what each pin does. Also, is there a standard type of jack that will plug into the port? If so, what is it called so I can ask for one in a store? I would be greatly appreciative if anyone could give me this information or tell me where I could find it.

I've seen a fair bit of stuph about it scatterred around in _Mapping the
Atari_ from Compute! Books (The older editions have nothing on it). I only
have an old-style 800 (considerably modified), so I haven't been able to
verify any of it.
It think the XL ROM's are supposed to look at the port for some ROM, and,
if it is there, it is banked switched onto the place where the floating-
point library usually is, and executed. You can make it install a new device
driver that way. Very convenient (compared to AUTORUN.SYS files).
I don't remember any of its other capabilities. This is all from memory,
so don't quote me on it.

Ron Harding.

1898. Re: Atari 800XL Parallel Bus Documentation

Newsgroup: comp.sys.atari.8bit

From: ehs@jumbo.dec.com
Message-ID: <13549@jumbo.dec.com>
Source record: 116202

There was a series of articles in Antic about the XL parallel bus
interface. Here are the notes that I made at the time:

The Parallel Bus Revealed
Earl Rice
Antic, January 1985, 45-47, 75 (generic device handler)
Antic, February 1985, 68-71 (hardware interface)
Antic, March 1985, 69-72, 76 (design of serial I/O board)
Antic, April 1985, 49-52, 78 (ditto, plus software driver)

Specifications for the parallel bus interface and Generic Parallel
Device Handler provided in XL-series machines. Example project
is hardware (USART) and software (MAC/65) for a serial interface.
All articles are full of obvious typos, esp. the diagrams.

I think Earl Rice had been associated with Atari engineering. As I
recall, the articles were not exactly lucid but started making sense after
several readings. I don't know if or how back issues of Antic are
available.

Why do these requests to be added to a mailing list (which doesn't
exist yet) get posted to the net??

Excuse me for putting all of this into one message, but I'm on a 300-baud terminal by long distance telephone and I'm trying to get things done in a hurry...

(1) I don't know for sure where the Internet archives are. Can anyone post the location?

(2) About the person with the question about LISTSERV, whose address got munged by someone's mailer:
I'll try to check on the problems, but as I said I'm not physically at Bucknell now. I'll let you know what I find over the weekend, I hope. Sorry for the inconveniences.

(3) Can anyone tell me where I can get a program called
The Atari Planetarium? I tried to buy it from MicrOTyme and ComputAbility, but both of them say that they no longer stock it, despite advertising it for months (in one case, they still are!)

(4) My annual question: Does ANYONE out there use a language called Advan BASIC ? If you do, I'd like to hear from you!

(5) Anyone know if the new Atari DOS is out yet? I read somewhere (I've forgotten where) that it was, but the February issue of ANALOG says that it isn't. What's going on?! And when it does come out, will we have to pay full price or will there be some sort of trade-in policy like the change from 3.0 to 2.5?

Post or mail any comments or further questions.
If this address disappears (though I'm not expecting it), try shafferj@amethyst.bucknell.edu

This, also, is for the person apparently at Xerox.COM whose address
came to me with a '.' in the username and '.Houston' tacked on to the
end of the domain name.

(1) 'superunarc.uue' is an invalid filename. The name is SUPUNARC UUE
Please note the eight-letter limit and the lack of a period between filename
and filetype. This is an IBM-imposed restriction and I don't like it either...

(2) If the server says that a file is not yet available, it means just
that. I'm not handling archives any more. The search is underway for
someone on Bitnet to do it. Anyone interested? Contact
jrd@stony-brook.scrc.symbolics.com
It's fairly easy. All the hard work has been taken care of by me
in starting up the archives in the first place.

(3) The server now is telling me that the filelist isn't available!
I don't have a clue what's going on here, and no time to track it down.

--Jim

PS: Being Bitnet archive maintainer DOES NOT require access to the Internet.
John Dunning (the aforementioned JRD) will mail the files to you, and
you mail them to LISTSERV. The reason we need someone on Bitnet is
because we haven't been able to get LISTSERV to recognize Internet addresses
as valid list-owner addresses. It's apparently the length, again... :-(

PPS: The column with the V's and F's and whatever...
It has to do with the organization of the files on the IBM. It means nothing

The mailing list does exist. People can subscribe by sending me mail.
However, some people have been posting requests to get added to the
list. I ignore all such postings (unless I flame them :-) in an attempt
to keep their volume down.

Date: Thu, 2 Feb 89 23:44 EST
From: Jim Shaffer <SHAFFERJ%BKNLVMS.BITNET@Forsythe.Stanford.EDU>
[...]
(1) I don't know for sure where the Internet archives are. Can anyone
post the location?

Ok, folks, here it is again:

The 8-bit program archives live on host Score.Stanford.EDU, in directory
PS:<INFO-ATARI.8-BIT>. For those of you whose hosts don't yet grok
domains, Score's Internet addresses are 10.3.0.11 and 36.8.0.46.

To get stuff out of the archives, use your favorite FTP program to
connect to Score, and log in as ANONYMOUS, with any password. Set your
default directory (in Un*x-speak, 'cd', in TOPS-speak 'connect') to the
above-named directory, and get a directory-list. At the top, you should
see a file called "-READ-.-ME-". Read it. It tells you what files are
where, and how to tell what tools you need (UUdecoders, ARC unpackers
etc) to use them.

That's about it. Please send any problem reports to me.

If anyone has stuff they'd like to submit to the archives, send it to
me, preferably with docs etc, and I'll see that it gets in.

For those of you without Internet access, the BITNET version of these
same archives is open for business, as LISTSERV@VM.TCS.TULANE.EDU. Due
to various difficulties, it doesn't yet contain all the stuff that the
Internet one does, but it will eventually.

Keep those cards and letters coming...

That's interesting... the latest (Feb?) issue of Antic says it is, has a review of it, and gives an address to write to. Costs $10, and I expect to order it tonight. It is called DOS XE, but I think it works with XL's as well. Not 400/800 - it makes extensive use of RAM under the ROM; there is no DUP.SYS to swap in and out. Has subdirectories, and supports the XF551 (the new floppy), which is my major interest.

> at home and can look it up for you.

The articles did *not* describe the parallel expansion bus on
the XL. They described the bus in the 1090 expansion box which has
several differences (buffers, power, a couple of new signals). You can
use the information to figure out what is actually on the expansion bus
just don't expect it to be a 100% match. The software driver information
applies to both the expansion bus and to the 1090 bus.

I don't think Atari ever "officially" released any info on the
expansion bus. There was a very nice manual written up on the XL (OS,
hardware, etc) but it died about the time Jack bought Atari.

Yes, the Atari DOS XE diskette and manual are available from the Customer Relations Department ($10 + $3.50 S&H). A demonstration copy has been sent to each of the user groups, so you may be able to check it out before ordering.

DOS XE works only with the XL and XE series of Atari 8bit computers (i.e. it does NOT work with the original 400 and 800). A portion of the operating system is stored under the ROMs to keep MEMLO down to a "compatible" level.

Actually a vote was taken on whether ZMag and/or ST Report should be posted to the group. It was decided that it was not in the net's best interest to do so, and I for one don't feel that has changed. As long as they are and with the frequency they're released, that's an incredible load to the network. If need be, perhaps start a separate newsgroup and let individual sites decide, but please don't put comp.sys.atari.st at risk. Both are available on MANY BBSs, as well as GEnie, CompuServe and other pay services.

Both MAPPING THE ATARI (Revised Edition -- which I refer to as MTA+)
and the articles themselves (ANTIC) portrayed the diagrams/information as
pertaining to the XL bus (known as the Parallel Bus Interface - PBI). No
where in the articles is the 1090 even mentioned. BTW, MTA+ says the
information is from the ANTIC articles. ANALOG also had an article on
adding 2K (of static RAM) to a 600XL. I did discover a difference between
the pin-outs in the ANTIC article(s) and the ANALOG article. (I suspect that,
in fact, the pin-out from the ANTIC article WAS the 1090 pin-out, and the
pin-out in the ANALOG article was from the PBI, itself. Can anyone confirm/
disprove this?) If anyone needs them, I can supply months and pages from both
magazines. (The mags are in my apt. and I'm at work, so they're not currently
accessible. I just looked through the ANTIC articles last night. I wish I
had written that stuff down...20/20 hindsight, as usual.)

I have heard of several people claiming to have the XL Addendum to
the Technical Reference Notes, or some such thing. I would be very interested
to know where one could pick these up. On the other hand, the manual that
comes with the XE (at least the 130XE; I can't speak for the 65XE or the XEGS)
included pin-outs for ALL the ports on the computer...nice touch.

Jim

Got a couple of questions if you don't mind:

1 > GET SUPERUNARC.UUE
List SUPERUNARC.UUE does not exist. Try sending a "List" command to get a
description of all lists.
I sent for this file and both ATARI8-F shows it as being available and the
VERBINDX shows it available but I still get the error msg above.

2 > GET DDOT2DOC UUE
File "DDOT2DOC UUE" is not yet available.
Again both documents show it available but I get the above msg.

3 In the ATARI*-F list the 5th column over shows a FP or a P.. what does
that mean. I've tried looking the documentation over several times to
avoid sending you a silly note asking for something that is already
explained and I can't for the life of me see the explaination.

4 The files that show a size of 0 I assume means they are somewhere but not
on TCSVM. Can they be put online or should I look elsewhere for them?

Sorry to bug ya with all these questions but I am new here and I just need
to get a handle on things. Thanks for your time and patience.

The Antic articles were definitely about the 1090, they worked
on it. Unfortunately they didn't state in the article that the
information was for the 1090 not the PBI. All the information on the
software interface applies to both the 1090 and to the PBI.
Synapse Software received one of the beta test 1090s with a 64K
RAM card and 80 column display card, they sent it and the docs to me
when I was working on SynFile release 2 (a special version for expanded
XLs and the 1450XLD). The only real problems with the 1090 were the
size and the projected cost. Unfortunately it died along with the 1400
and 1450 when Warner sold Atari.

> I have heard of several people claiming to have the XL Addendum to
> the Technical Reference Notes, or some such thing. I would be very interested
> to know where one could pick these up.
Warner Atari had re-written the Technical Reference Notes for
the XL series. The draft copies I looked at were very nice, spiral
bound, with a lots of examples and a very well commented OS listing.
Another victim of the sale, they were never published.
There were also some short (<50 pages) manuals on the XL
hardware and OS. Some developers and software houses (Synapse, EA,
Broderbund, etc) got copies. As far as I know those manuals are the
only "official" doc that was ever released.

From: hamilton@HUDSON.DEC.COM
Message-ID: <8902101704.AA01690@ucbvax.Berkeley.EDU>
Source record: 116079

Does anybody have information on a TRAK drive?

I just obtained a TRAK AT-D2 drive which has a printer port built in. The 'connector' at the back of the drive is an edgecard with 17 fingers on top and bottom. I went to RadioShack and got their printer cable for MOD I/II/III/IV which is a ribbon cable with an edgecard connector on one end and centronics-type on the other. The computer does not 'see' the printer.

TRAK is apparently out-of-business (no answer at phone number in manual and no listing when directory assistance was called). Does anyone have the printer port pinout for this beast?

1926. Atari 8-bit battery power supply

Hello! I have tried to post this once before. I believe it was destroyed.
I am looking for information on constructing a battery-powered, portable
130 XE. The main problems I face are the power input and the Video output.
It is possible that I will be able to use it will emplaced video screens,
therefore that part is not as essential as the battery power.

I would like to be able to use a set of 9 volt, C, or D batteries
(preferably 9 volt), to power a 130XE computer. Any plans or (preferably)
schematics for such a device would be, to say the least, greatly appreciated.

Internal power supplies would be best.

On the subject of video output, any form of output to a low-power LCD
screen (such as used in the Toshiba 1100 and other, similiar Laptop
machines) would be wonderful!

Thank you for any help you can give.

A while back I posted a message about the percom drive and porgramming the controller to understand enhanced density. Well, I was told that it could be done. No I am requesting any info anyone may have on the percom controller. I can find my info on the controller, so I am not reallly able to start. If anyone has attempted such a project please let me know.. Thanx..

1928. Re: Atari 8 archives

Newsgroup: comp.sys.atari.8bit
Date: 1989-02-12 06:06:18 UTC
From: andrewh@dasys1.UUCP
Message-ID: <8680@dasys1.UUCP>
Source record: 116082

Pardon my lack of experience, but can anyone give me instructions as to where and how I can get programs for my 8bit? I especially need a Uudecoder and a uuencoder--the versions of Yau and Yaue that I have appear to have bugs in them.

Also, does anybody else have trouble unarcing files using SuperUnarc that have been unarced on other machines? I archived text files (in the crunched format) on my UNIX machine, but upon getting them to my 8bit, they come out garbled. The problem does not appear to be in the file transfer process--I uuencode the file, dl the file using Ascii file xfer (I don't trust Kermit too much), then uudecode it. SuperUnarc can't even recognize the individual parts.

Any help would be appreciated. Gracias.

When I requested a file list from the archive server, the printout it sent me was riddled with holes and promises.... and a few pieces of software that unfortunately have been in my library for a while.....

Ok, here we go again. Please, everybody, I know you're all anxious, but things take (often unreasonable amounts of) time.

The state of the BITNET archives is as follows: The LISTSERV is up and running, and a small amount of the stuff in the Internet archives has been loaded into it. It does NOT, repeat NOT contain everything that it's supposed to yet. It's not possible for me to just shove everything into it, as I don't have direct access to the BITNET, and the LISTSERV software requires direct access for loading things into its database.

I have some volunteers to take over the work of inserting files into the archive, and we're currently working on getting the LISTSERV to understand that they're authorized to do so. When things get going again, I'll send another announcement.

Do the archives accept uploads? :-)

Sure, just send 'em to me. They'll get there eventually.

From article <3806@druwy.ATT.COM>, by dlm@druwy.ATT.COM (Dan Moore):

| The Antic articles were definitely about the 1090, they worked
| on it. Unfortunately they didn't state in the article that the
| information was for the 1090 not the PBI. All the information on the
| software interface applies to both the 1090 and to the PBI.
| Synapse Software received one of the beta test 1090s with a 64K
| RAM card and 80 column display card, they sent it and the docs to me
| when I was working on SynFile release 2 (a special version for expanded
| XLs and the 1450XLD). The only real problems with the 1090 were the
| size and the projected cost. Unfortunately it died along with the 1400
| and 1450 when Warner sold Atari.
|
|> I have heard of several people claiming to have the XL Addendum to
|> the Technical Reference Notes, or some such thing. I would be very interested
|> to know where one could pick these up.
| Warner Atari had re-written the Technical Reference Notes for
| the XL series. The draft copies I looked at were very nice, spiral
| bound, with a lots of examples and a very well commented OS listing.
| Another victim of the sale, they were never published.
| There were also some short (<50 pages) manuals on the XL
| hardware and OS. Some developers and software houses (Synapse, EA,
| Broderbund, etc) got copies. As far as I know those manuals are the
| only "official" doc that was ever released.
|
|
|
| Dan Moore

Dan,

Thanks for the background information. I always enjoy reading some of
the Atari history, especially from an 'insider'. You have been a real
credit to the Atari 8bit user community over the years and I appreciate
it. I'm only sorry to see that third party software companies have
virtually abandoned the 8bit market. I know that sales dictate the
direction a company takes, but from the users and User Groups that I am
involved with, I know that there is still a small but solid market if
anyone wants to take advantage of it.

Any comments on the ATARI lab kits? When I was in San Antonio last week,
a Federated salesman gave me a flyer from a store that had the starter kit
(temp probe) and light kit togather for $29.95. My wife uses our 400 in her
Kindergarten class. The kits say 16k cartridge. Will the kits work on the 400?

A few questions...

This went around a while back (or was it in the ST group)... I would like to exchange ASCII files between the 8-bit and a PC. Is this possible? I have a 1050 and an XF551.

Also... I read that using the paddles in quick-scan mode as opposed to normal involves just setting a bit in one register. It is really that simple?

I have a short addendum to the Tech Ref manuals that discusses the XL.
I believe I sent Atari $12.00, and they sent me a book with some
info on the new features of the XL OS. I also think it was mostly oriented
towards the 1200XL. However, I don't remember anything about the PBI.
(I don't think the 1200XL had the PBI, but I can't remember.)
I also don't know if the book is still available. I got this a few years
ago.

>schematics for such a device would be, to say the least, greatly appreciated.

Gook luck. Your gonna need it. The problem is that the 6502 CPU in the Atari
is made in NMOS technology. NMOS is not the power miser that CMOS is. I don't
know this for sure, but I suspect that all of the major chips in the 130XE use
NMOS. I do know that the power supply for the XL and XE computers is rated at
5 volts, 1.5 amps. Small batteries aren't made for such a high current draw.

A 9 volt battery definately will not suffice. When my power supply blew
~2 years ago, I went to Radio Shack and bought a 6V lantern battery, and hooked
it up to the power connector directly. This only gave me about 5 hours total
usage before it started dying. As it died, the voltage dropped, and I had to
constantly adjust the color trim pot to keep the background color blue.
So, if you want battery power, you will need 2 things:
1) A BIG battery. It should have a larger Amp-hour capacity than the lantern
battery I used.
2) A voltage regulator, unless you don't mind constantly adjusting your color
trim pot as the voltage drops. :-)

Unfortunately, a battery powered Atari is not a reality.

>On the subject of video output, any form of output to a low-power LCD
>screen (such as used in the Toshiba 1100 and other, similiar Laptop

Again, this is not meant to be. The GTIA chip only puts out NTSC video
(in the USA), and I don't think there are any NTSC compatable LCD screens
readily available. If anyone knows of any, please let me know.

1936. Atari 850 help

Newsgroup: comp.sys.atari.8bit
Date: 1989-02-17 18:25:53 UTC
From: phil@calvin.EE.CORNELL.EDU
Message-ID: <950@calvin.EE.CORNELL.EDU>
Source record: 116090

I'm in the process of building an 850 interface lookalike, but I need
to know the various commands that an applications program would send to
the 850 handler (i.e.
XIO 34,0,etc.)
and their meanings (as in what bit in the aux bytes sets what). Not having
access to someone who owns an 850 manual, all I know is what I can glean
from the source code for some terminal emulators.
I want to write a handler for my interface that is identical to the 850's
from a terminal emulator's point of view, for compatibility reasons;
thus, the desire for a list of all the valid 850 commands and the
meaning of the AUX bytes associated with them.

If anyone on the net has an 850 manual lying around and could e-mail me
the codes located in there (under "programming info", I suppose), I would
be very grateful.

Thanks in advance,

Help!

We gave my brother a Macintosh for Xmas, and I promised him (without understanding the details of how) that I would get his text files converted from his Atari 800XL onto the Mac. WELL... I discover this is not as easy as one might believe ..

I have here two boxes of disks, his files, in ASCII format (some format that Atari lets you put files into ...). I have not yet bitten off the job of building a serial line interface from the atari onto some other system.

Here it is. If you can help me, lets work out a deal. I can deal with this text on IBM-PC, Mac (final destination) or Unix tar tape. If you can get it from Atari 5 1/4 disk into one of these other forms, I will pay some bucks, and be most grateful, all at the same time.

Please drop a note or call.

It's pretty easy to transfer the files.

What I did was to get a hold of an old R-verter interface (a really cruddy modem interface for the 8-bits), and reverse pins 2 and 3. Voila, instant null modem cable! It hooks up directly to the 8-bit via the SIO port, and to the RS-232 machine (in my case an ST). Then just load up term programs and transfer the files to the Mac.

I'm not sure, but did you say that the Atari files are in ASCII? Did you use Atariwriter + to do this (CTRL-S I think). Then there should be no problems.

I might be willing to sell my null modem cable, complete with software. Leave me a mail message.

I forgot to mention that you need a modified term program for the 8-bit to do this transfer. Mine is a modified AMODEM 7.5 (or so) with a little fix by Bob Puff (of Diskcomm fame).

RE: xfer of 8bit text files to other computers...

The easiest way to do this is to upload the text files to the net, or a BBS and then download them. (On the net send them as mail to yourself, same for a BBS.)
ALL the other ways to do this involve some expensive hardware, except for building a null modem cable to go between the computers and then you have to know the exact port configs and write some software for the xfer.

Good Luck

To the people needing to transfer files.... All you need to do is get a modem
for the Atari. You can pick up a 300b modem for $30 or less mail order,
with software, and then upload to any PC or even to PORTAL for downloading.
If these are unapplealing, send me the Atari disk, and the IBM disk, and
I will transfer them for you!!! :-) I can always use extra ca$h!

Transferring files from an 8-bit Atari to another computer CAN be fairly simple..

A lot of it depends on the equipment you have available. If you still have the 8-bit Atari *and* a working modem setup, you're home free... you can use the modem to transfer the files to the other computer and its modem.

Set one computer up at one house and the other at another, then use any good terminal program to call up and upload the files. If you have two telephone lines in the same house, even better. Just call the other line with the other computer on that line. (This is how my 800 talks to my ST)

If you have an Atari 850 Interface, or a P:R: Connection interface for the 8-bit Atari, you can dispense with the modems and use a "Null-Modem" device to connect the computers directly together. All a Null-Modem is, is a connector that routes the Send and Receive lines to the proper places. I'm not sure, but Radio Shack might have them..

Another thought.. before you spend any bucks, there might be a local Atari users' group nearby which could help you.. Email me your city, and I can try to look up the closest group.. these mutual support groups will often go out of their ways to help people in just these situations..!
(I know... I do it all the time for my user group)

I was one of those asking about writing IBM-compatible disks on the 8-bit. No one seems to have a way of using unmodified hardware, even with an XF551 disk drive. I really need to do this if possible, as the 8bit is at home and the PC is at work, and I would prefer not to use asynch as I don't have a modem.

I have the atari tech notes coming in the mail (finally), and hopefully will be able to figure out how to do it myself. Anybody know how to get docs for the IBM PC/MSDOS (preferably for free?)

Wish me luck. -Stan

From article <374@ultb.UUCP>, by clf3678@ultb.UUCP (C.L. Freemesser):
> I don't know about the other carts, but I do know that Dark Chambers has
> not been released yet.
>
I was just at out local User's Group Monday evening and our resident software supplier has several new cartridges with him (that I had never seen before). They were:
Dark Chambers
Into the Eagles Nest
Crystal Castles
Mario Brothers
Crime Busters (needs light gun)
>
> PS: What exactly is Dark Chambers about?

Our supplier let us demo two of the cartridges. The first, Dark Chambers, is a 'Temple of Apshi' type of maze game with 30 some levels (rooms). It can be played at three different skill levels and seemed very nice.

The second games was Crystal Castles, which seems like a nice game for children in that it has a cute sticky bear figure and doesn't require lightening quick reflexes. We didn't spend much time with this one because the meeting was winding down and people were leaving.

He was selling for Dark Chambers for about $32.95. Crystal Castles wasn't quite that high. When Atari first mentioned all the new cartridges that they were coming out with, they were supposed to be in the $19 - $24 range. What happened? Maybe they think they can get more because Nintendo cartridges are more expensive. All I can say to Atari is: (in the words of Lloyd Bensten) "I have played Nintendo games and these are no Nintendo games".

That criticism aside, I am glad to see that the dam is busting loose and cartridges are arriving. I'm looking forward to seeing Crossbow and Air Ball.

>PS: What exactly is Dark Chambers about?

Matt Ratcliff left a fairly detailed review of the Dark Chambers XEGS cartridge on the 8-bit Atari Forum on CompuServe..

Apparently it's a multi-level "Dungeon Adventure" type game.. it sounded pretty good from what he said about it... I hope it's released soon, as it's about the ONLY one of all the cartridges released recently that is a truly NEW game..

If anyone still needs help in transfering files from the Atari 8-bit to Macintosh, IBM, ST, and Amiga formats, I can help. I have a program that will convert text files among various computers and I have a ton of hardware to assist me. I also have access to IBM's, Macintoshes and Amigas (I'm at college), as well as ST's (my roommate has a Mega ST2).

If you would like help, call me at 716-475-4088. I run a bulletin board from this number, so if you don't have a modem, then contact me at one of the electronic addresses below, preferrably through BITNET.

Adios!

One thing that everyone keeps forgeting is the fact that the 8 bit doesn't store ascii quite the same way as a Mac or IBM does. Unless these files where already converted, then the will have to have the atascii returns converted to ascii returns. Even if they program you used said "save ascii" it may still have used chr$(155) for a carriage return.. I wouldn't jump to conclusions on how "easy" converting files from one computer to another is. Escpecially if it going from on program to another. (say Synfile to Paradox) They may both save ascii, but that doesn't mean that the ascii files are compatiable..

I agree with the general idea of the discussion, all the things that
have been suggested hardware wise look good, but my experience with
atari 8bit terminal programs is that they don't mesh with the terminal
programs of other computers. My dad and I spent about 4 hours engineering
a program on the atari that would send a syn file program over to an Amiga
database (True they were different types of applications, but the data files
were almost exactly the same.) After that he spent hours trying to
get the database to accept the data our atari had sent it. The moral
of the story? Well if you are really set upon sending data from one
computer to another you can, but it is harder than it sounds.

Message-ID: <381@ultb.UUCP>
Source record: 116108

Isn't it feasible that Atari has to hike up the prices on some carts because of the cost of royalties to publish these games? I mean, games like Crossbow and other non-Atari created games will cost Atari $$$. Still, Atari games are the lowest priced carts on the market. However, seeing that you can get older 800/XL/XE carts for $3 each from mail order houses, paying $30 for a carts, no matter how good it is, seems a waste.

=cf=

BTW, a question for the techies: I've got a 600xl that I have been thinking about upgrading to 64k (I only use it to play a few carts right now). If I buy the 1064 expansion module, will it give me TOTAL compatibility with the 800xl? What I mean is, will the computer act just like a 600xl, or because the memory is in a "different" place, will I have problems running >16K programs?

In reference to the ATASCII C~R 155 v. ASCII CR 12 (or 13?)...

I have a very good shareware program called SDVERT.COM that runs under SpartaDOS 3.2. It will convert the CR/LF sequence from one form to any other, for about 5 different types of machines... it will strip out the ATASCII 155 and replace it with either an ASCII CR, or LF, or both.

If you need it, send me net mail....

1957. High-frequency hum when using Concurrent I/O

Newsgroup: comp.sys.atari.8bit
Date: 1989-02-26 18:02:42 UTC
From: charles@c3pe.UUCP
Message-ID: <6542@c3pe.UUCP>
Source record: 116111

Ever since I started using my terminal emulator, I have noticed a medium- to high-pitched hum when it starts up concurrent I/O mode. Unplugging my ICD P:R: Connection makes the sound go away, which leads me to believe it is being generated by the serial interface, and not by the 800XL CPU.

Has anyone else been bothered by this? How about 830 owners? Is there a fix?

Please Email replies and I'll summarize.

Thanks, Charles Green charles%c3pe@decuac.dec.COM

1958. Transferring files, ATASCII <--> ASCII, et al

Newsgroup: comp.sys.atari.8bit
Date: 1989-02-26 18:59:14 UTC
From: Chris_F_Chiesa@cup.portal.com
Message-ID: <15132@cup.portal.com>
Source record: 116112

Gentlemen, gentlemen, gentlemen...

Really. Such fuss: "modify the hardware;" "write your own software;"
"set up one computer at one house, the other at another;" etc etc.!

Those who suggest a null-modem cable are on precisely the right track,
but are unnecessarily complicating the matter by crying the alarm over the
ATASCII EOL (CHR$(155)) character vs. ASCII CR-LF sequence, in the matter
of text files.

All you need do, once the null modem cable is in place and "ready to go,"
is use a terminal program that includes a file-transfer protocol AND, on
the Atari side, the capability to distinguish between "binary files, no need
to 'convert' CR/LF and EOL", "text to be converted," and possibly "text to NOT
be converted (e.g. what people keep saying AtariWriter+ can generate with
what, the Control S option? I may be wrong here)."

I know whereof I speak, also: I regularly transfer all types of files: Atari
text, non-Atari text, Atari binaries, and non-Atari binaries, FLAWLESSLY back
and forth between my Atari XL and my Amiga 1000, through a null-modem cable,
at speeds up to 9600 baud, using Kermit protocol.

Kermit allows you to set "file type" to "binary" or "ascii (or 'text')" --
and, on the Atari implementation of "Kermit65," to "ATASCII" ! (There's even
a nice doc file for Kermit65 that spells out quite nicely just WHEN you need
to use each setting.)

Personally, I recommend running Kermit65 on your 8-bit Atari, and whatever
Kermit is available/necessary for the 'other' computer. It exists for nearly
EVERY computer I've ever encountered: Vax/VMS mainframes, Unix machines (most
if not ALL flavors), Mac, IBM PC, and of course Atari. (Kermit65 for the
Atari, incidentally, is frequently posted to this very newsgroup, if you've
managed to miss it so far.)

The *ONLY* kludge necessary as far as hardware is concerned, is that you need
"something" to make the Atari serial-I/O port compatible with a "standard"
RS-232 port. I use the 850 Interface Module with the usual Interface-Module-
9-pin-jack-to-RS232-25-pin-jack cable on the Atari side, and straight into
the back of my Amiga on the Amiga side. Basically, get your Atari and the
"other" computer into whatever configuration WOULD NORMALLY allow you to plug
an off-the-shelf modem onto each, and then instead of plugging in a modem,
connect the null-modem cable. This works BEAUTIFULLY, from personal and
immediate experience. (In fact, I now do all my BBSing and mainframe/Net
chatting with the Amiga, including downloading any Atari binaries -- then I
transfer 'em over to the Atari later, offline.)

Good luck, all, and write me here if you need any details. I haven't had a decent chance to help people with computer questions since I graduated from college and had to take a real job, so I'm eager to assist!

Chris Chiesa

By the way, to 'bartlett' who originally posted here: did you receive my two multi-page E-mail messages regarding details of null-modem cable construction, sent from 'cfchiesa@bsu-cs.UUCP', or do I need to send them again? Same question to 'yehuda@solarium', I sent them to YOU too.

1959. SpartaDOS X question

Newsgroup: comp.sys.atari.8bit
Date: 1989-02-28 00:47:00 UTC
From: BIW109@URIMVS.BITNET
Message-ID: <8902280051.AA03433@ucbvax.Berkeley.EDU>
Source record: 116113

Over the past weekend I baught the new SpartaDOS X cart. and have
a question about it. It is supposed to support the 1050 drive with
the UD Doubler (among other drives). Naturally, I wanted to see how
much faster the us doubler was (up to now, I have only used the doubler
double density with MYDOS). I formatted a disk with the high speed
sector skew (in SpartaDOS format). I couldn't use the copy command to
move files onto the disk (it doesn't support disk swapping) so I had
to use the menu command (actually I have two drives, but one is at home
on a make-shift computer and the other one is at school on the 'real'
computer). I put a machine language program onto the disk, and it did
seem to write it real (put that in itallics) quick. Great, I thought,
and tried to run it. Well, it loaded and then just sat there (great,
the worlds most advanced paperweight). I thought I must have done
something wrong, because the program runs just fine off of the atari
dos disk. I reformatted the disk, only this time I used the atari
format instead of the Sparta format (but I still used the high speed
sector skew). It worked, but I didn't get the high speed loading...
Also, in both cases the file was shortened when it was copied. I know
it is probably because the file was appended, the only problem is that
when I tried to copy it onto the Sparta format disk, it was shortened
MORE than when I copied it to the atari format disk.(?) I would greatly
appriciate any help on this problem. One of the main reasons I wanted
the cart. is for the high speed data transfer, aside from all of the
goodies in it. Now might be a good time to bring up an old plea, if
anyone has a schematic for the 1200xl (ACK!) I would be willing to trade
some dead presidents for a copy of it....
Many thanks
Raymond Courtois

1960. OmniCom at 2400 bps?

Newsgroup: comp.sys.atari.8bit
Date: 1989-02-28 19:37:57 UTC
From: njd@ihlpm.ATT.COM
Message-ID: <3109@ihlpm.ATT.COM>
Source record: 116114

I have a question for users of the OmniCom 80-column VT100 terminal emulator. (I know that there are some of you out there!) Anyone who knows how to set up an 850 for different RS-232 speeds may be able to help, too.

I have been using OmniCom for several years now, and recently acquired the standalone ("shareware") version. I want to "upgrade" to a 2400 bps modem, but _will OmniCom work at 2400 bps?_ The documentation says that the program may have trouble handling continuous incoming characters at _1200_ bps, if there are no pauses (say, between "screenfuls" of lines), under some conditions. (It also says that OmniCom will use ^S (X-OFF) / ^Q (X-ON) flow control to keep from losing characters. Of course, if the host computer takes too long to respond to ^S, characters will be lost.) I have never experienced a problem like this at 1200 bps. Also, I seem to recall David Young (CDY) saying (a year or two ago? sometime before he "retired," anyway) that he had been working on improving OmniCom's speed, even to handle 2400 bps.

If it will work at 2400 bps (even with possible occasional loss of characters, but I would hope that file transfer, i.e. Xmodem and Kermit, work OK), does anyone know what to set the 850 I/O parameters (or whatever they're called) for 2400 bps? OmniCom has no speed setting for 2400, only 300, 1200, or "custom" for user-specified I/O control parameters for the 850. I imagine that any program that sets up an 850 for 2400 bps would have to use the same (or similar) values.....

I want to know if 2400 bps will work before I spend money on a 2400 bps modem (I suppose I could try to borrow one, but I still would like to know if there is any hope of success.)

Thanks in advance for any help or information.

From: njd@ihlpm.ATT.COM
Message-ID: <3110@ihlpm.ATT.COM>
Source record: 116115

I have read and heard that the Diamond graphical environment cartridge (for the 8-bit Atari computers) has been shipped in small quantities (several hundred). Does anyone know if the GOE cartridge (from Total Control Systems, that is, David Sullivan) has been shipped to anyone yet? (Do any reviewers, etc. have it? My impression, from reading various reviews and articles on these two competing graphical environment systems, is that GOE _may_ turn out to be superior to Diamond, if Sullivan could just get it out the door!)

I know that in the Feb. [correct month?] issue of Atari Interface Magazine (formerly Michigan Atari Magazine), there is a full-page ad for GOE. (No, I didn't read it, I "talked" on-line with Pattie what's-her-name of Unicorn Publishing.) I am supposedly on TCS's mailing list, which means I may get some info about GOE soon, if it has shipped. But, does ANYONE actually have one (even as a review copy)? If so, I (and the members of my local user group) would like to hear anything you can tell us about your impression of GOE. (Or tell us what issue of what mag. your review will be published in and we'll _buy_ it!)

Thanks in advance,

Date: 1989-03-01 03:19:13 UTC
From: gdtltr@vax1.acs.udel.EDU
Message-ID: <2959@udccvax1.acs.udel.EDU>
Source record: 116116

I have used Omnicom at 2400 with little problem (though I normaly use Kermit65). The custom option lets you set your baud by the parameters of the set baud XIO command. I don't know the number off the top of my head, but you should be able to find it in your 850 manual. The only reason XON/XOFF has to be used is the slow 80-column screen handler. Scrolling is particularly bad since it has to move a whole screenfull of bits. This isn't a problem with Kermit and Xmodem since they don't print the data to the screen. Your best bet, if you can do it, is to configure the system you are calling to clear the screen as much as possible instead of scrolling as it will go much faster. XON/XOFF speed isn't too bad a problem unless you are going through a network or two that don't support it (transparant). Also, in case you are thinking of using a PLATO system in ascii mode, don't bother. Control-Q is SHIFT-STOP on PLATO, so everytime the screen scrolls a few times in a row you will get kicked out of whatever you are doing. Not a fun experience. You may also consider picking up Kermit65. Flow control is optional in K65.

From: BIW109@URIMVS.BITNET
Message-ID: <8903020006.AA18901@ucbvax.Berkeley.EDU>
Source record: 116119

I have fogured out how to get machine language programs to load
with the SpatraDOS X cart., but now I have run across a strange
problem I can't quite figure out. I put a vt100 terminal on a newly
formatted disk, and then I put a config.sys file on the disk with
the command COPY CON: CONFIG.SYS. I then ran the vt100 program with
the command X VT100.OBJ. I wanted to see if everything was ok, so
I logged onto the schools system and did an ascii capture. I also
wrote a default file and a macro key file to the disk for the terminal
program. I then got a directory of the disk. The ascii file I had
just captured was over 200 sectors long! I knew this was wrong because
it was only four or five screens worth.. I went back into dos and got
a directory, and the ascii file, the config.sys file, the macro, and
the default file were all over 700k long! Some simple arithmatic will
tell you that 4 700k files do not fit on a 180k disk... The terminal
program works, because I have been using it for a long time with MYdos,
and it works fine. What bothers me is that a file put there by sparta
dos it self didn't seem to work right... Aside from this problem, I
still can't get the terminal program to load with the faster data trans-
fer (the X command seems to dissable it..). If anyone can help me, it
would be greatly appreciated... Otherwise, I think the disk based
version of sparta dos is starting to look very good....
Thanks, Raymond Courtois

Instead of trying to fix a 1027, you would be much happier trading it in.

Send the printer, plus $75 to Atari, and they will send you a brand new XDM121 daisy wheel printer. Although not well known, the printer is supported in AtariWriter+, and is quite capable. Considering the poor design of the 1027, an exchange is really the best way to go.

I'm not totally sure of the price, but maybe somebody from Atari can verify this.

From: Star-Raider@cup.portal.com
Message-ID: <15306@cup.portal.com>
Source record: 116121

Methinks the aforementioned problems dealt with the Atari text files being in ATASCI instead of ASCII... ergo the difficulty reading them even when transferring them over to a new medium. Before attempting to build the null modem cable and tranfer files, do yourself a favor and save the Atari files in standard ASCII format... otherwise you're asking for trouble.

In article <8902280051.AA03433@ucbvax.Berkeley.EDU> BIW109@URIMVS.BITNET writes:
>I formatted a disk with the high speed sector skew (in SpartaDOS format).
>[...] [The program] seemed to write it real quick, [...] tried to run it.
>Well, it loaded and then just sat there [...]

Some programs (as you found out) just don't work when used with SpartaDOS.
The ones that don't are programs which attempt to call DOS routines directly
instead of calling them through Atari's standard I/O mechanism. Granted,
their software runs faster, but it is less than DOS-independent.

>I reformatted the disk, only this time I used the atari format instead
>of the Sparta format (but I still used the high speed sector skew). It
>worked, but I didn't get the high speed loading...

This is because the high speed I/O is dependent on 2 factors: 1. the
disk is written with an optimal sector skew which allows the tracks
to be read "faster". Unfortunately, as you may have noticed, some unmodified
drives barf on this sector arrangement and will go up to 1/4 as slow as
without the skew. 2. When SpartaDOS detects that it has a drive using
the US Doubler (see the SpartaDOS manual, SIO calls), it will use its
own SIO handler instead of the internal one. For any drives with the US
Doubler, when SIO is performed to that drive, it sets the serial line speed
according to an index number returned by the US Doubler. Atari DOS loads
its own SIO driver (I believe it's for burst I/O), but it has no provision
to modify the serial line speed when accessing a drive with a US Doubler.

So, unfortunately, when you use the high-speed anything with Atari DOS,
you will get less than high-speed results. I did notice, though, that
the double density using the US Doubler on a 1050 disk drive is actually
FASTER than double density on other disk drives. These observations were
made about 5 years ago, so things may have changed now...

>One of the main reasons I wanted the cart. is for the high speed data

> Many thanks
> Raymond Courtois
>Bitnet: Biw109@URIMVS

The schematics to the computer won't help you with your quest. What will
help are two things: 1. "Inside Atari DOS" (forget the author) which
contains the source listing for DOS .. or the DOS that was posted here
a while ago. 2. Disassemble the SIO handler for SpartaDOS and examine
how the new SIO transfers are performed. You may, then, be able to
modify DOS so that it initiates high-speed I/O on US Doubler-modified drives.

What's neat about this problem is that it's entirely software-related.
You need software to activate the hardware...

1969. how do i transfer Atari 800 files to a IBM PC

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-04 22:53:11 UTC
From: spl@topaz.rutgers.edu
Message-ID: <Mar.4.17.53.06.1989.11671@topaz.rutgers.edu>
Source record: 116123

OK People here the problem. I have alot of assorted files for my Atari 800 computer stored on floppies and these same floppies are becoming quite old(going on 8 years) and I'm afriad that i will soo loose some of them to the rotting of the disk. I heard a couple of years ago that a disk only have a life expectancy of maybe five years, then the data's integrity becomes questionable. Here my question, Is there a simple way to transfer all of the files from the OLD floppies to a set of NEW IBM floppies? I relize that i cant use the IBM floppies in an Atari disk drive, but with the programs/ data on IBM disks i can take care of it and watch over it a lot easier plus i can compress it and store it on less volitale media. If ever in the future i waht to use the program again on my Atari, i will transfer them back.

One way i thought of doing it was via serial ports but i don't have the time to write programs for both machines. Are there any programs out there designed to do this? I know that i could us a modem program to accomplish the job but the only program i have to do this is an old version of AMODEM that have a max speed of a cranken 1200 baud w/XMODEM. I would like a program that i could leave unattended (hint: maybe Ymodem or some of that nature, you know something woth some protocol and something that will pass a filename).

If you see any solution to my problem please send me a reply, or even if you have idea on a way i can resolve it please reply.

- Thanx to whoever may solve my problem

Why don't ya just arc the old Atari files, then copy them over to freshly formatted Atari disks? Using double density will save even more room. This would accomplish the same thing without having to port back and forth to an IBM. If you didn't know that ARC programs are available for the Atari 8-bitters, check with the Atari forum on CI$... several pgms are available there that could help you.

Raymond,

I just recently purchased SpartaDOS X and have had no problems using it whatsoever. I use it with a 1MEG MIO, 2 20 meg hard drives, 2 1050's (one of them is US Doublerized), an INDUS GT, R-Time 8, 130XE, and an XEP80. oh yea, and an INCOMM 2400 baud modem. I've found so far that Sparta X runs nearly EVERYTHING (especially when using the X command). Is the VT100 emulator you are using Public Domain or Shareware? If so, can you post it to the net (or Email it to me) so I can try to duplicate your problem?

> LESNIEWSKI@CANCER
Well, If you have a copy of amodem, you can use a program on the PC
like procomm, mirror, or crosstalk. To connect the computers
together, use a modem cable(like the one that you have from your 850
to your serial modem) and reverse the connection on the RS232 side
of pins 2 and 3 and you can hook it directly to the back of the IBM
You can then modify the Amodem program to work at 19200 baud and voila,
you can transfer the programs. Look for the XIO 36 (I think that was
the number) commands.
Hope that make sense and works,
Mike

1975. Old Hardware and Software ... etc ...

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-06 15:51:00 UTC
From: ACSCHW@SEMASSU.BITNET
Message-ID: <8903061640.AA17219@ucbvax.Berkeley.EDU>
Source record: 116129

Hi everyone !,

I'm new to the group, so I'll introduce myself first.

My name is Curt Wilbar and I'm a junior at Southeastern Masacchusetts University. I'm majoring in computer science and I have had my Atari since 1982. I have a 400 with 48K, the A roms, GTIA, 810 drive with 'The Chip', 1050 drive with 'U.S. Doubler', 850 interface that quit working, and also have an 800XL and use my 400 more than the XL.

I use it mostly for games now, but it never sits idle too long.

I'm looking for any old software and hardware that people would like to sell. In hardware I'm looking for disk drives, 850 interfaces, an old 800 (not xl) that maybe never was expanded. In software, I'm looking for a couple of titles in particular: Threshold and Drol. However, I am interested in anything that you have to sell. (I'm not rich, so Don't tell me about the 1450XLD with 5 meg and a dbl sided dbl density 3 1/2" floppy that you sneaked out of ATARI R & D unless you want to sell it for a song)

Just let me know what you got, and if I want it and can afford it, etc, you got a sale.

I'm also interested in tech literature, especially on the 850 interface. I got mine without manuals, and after I fix it (anone out there do repair ?) I would like to make some cables and software, etc for the serial ports.

Here's a hard question: Anyone got any technical information out there on the original 'The Chip' and Arhiver/Editor for the 810 ?
Any custom written programs out there for them, etc.
When I purchased mine, the documentation said that they would be releasing tech notes, but when I called about a year later, 'We won't be realeasing that info'.

Forgive me for all the assorted quesionts, but here is another. Anyone ever hook up a hard disk to there atari, if so, what hardware/software did you use ? How about a 3 1/2" 720K or 1.44M drive ?

Last question: Have anyone had as many problems with the 800XL as I have. I currently have mine and a friends, and mine does not display dark colors very well, and tends to have lots of interference in the dark colors (I'm using a TV), and my friends 800XL has perfect color, when its in color, but a few hard beatings on the top of the case usually brings the color back. Now his 800XL when you tern the power on, it acts like the escape key has been locked down. (I think something sat ontop of the keyboard too long and did something to the switch). I don't know what most of you think, but these 2 800XLs are mid-early production machines, and are made in Taiwan. This is why I use my 400.

Also, is there public domain software on BITNET for the atari's, if so, where ?

Thanks (I know its been long),

Curt Wilbar

1977. mac 65 "save" format

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-07 03:16:31 UTC
From: rac@sherpa.UUCP
Message-ID: <14@sherpa.UUCP>
Source record: 116131

Reading John Dunnings request for the mac 65 de-tokenizer which Analog published awhile back reminded me of the following "memo" I wrote to myself after making a very time consuming mistake a couple of years ago. I wish I'd had the Analog article at the time. It would have saved me a lot of trouble.

In going over this after so long, I find some parts aren't very clear, and you will probably need some knowledge of the Atari dos disk layout for it to be of any use to you. The disk related stuff probably isn't relevent if you're using SpartaDos. Maybe someone else will find it useful.

Roger

MAC/65 "SAVEd" Source File Format.

I wrote this little doc file in case any of you ever need to recover a "SAVEd" listing of a MAC/65 program. One day while programming away, I assembled my object file on top of my source file (the only copy I had), seemingly destroying it. The source file had been 59 double density sectors long and the assembled object file was only 9. Since DOS doesn't actually delete a file when you write over it, but only marks it as deleted in the directory, I knew that the last 50 sectors of my file were still on the disk. YOU CAN BE POSITIVELY SURE OF THIS ONLY IF YOU HAVEN'T WRITTEN TO THE DISK SINCE YOU MADE THE SCREW-UP!!! So now I just had to figure out how to turn it back into a file DOS would recognize and MAC/65 would load. You can use any good sector editor to change the file links, etc.
Although I did lose the first nine sectors of my source code, fortunately I had an old listing which helped me in re-typing the first part of my program. Since the first portion of an assembly program is usually devoted to the equates used by the program anyway, figuring this out wouldn't be too difficult, so you could probably get by without a listing.
I used Disk Wizard II by C.A.P. software, for the disk editing.

This is the file structure MAC/65 uses when SAVEing a tokenized source file.

The first two bytes in a tokenized (SAVEd) MAC/65 source file are always "FE FE". This is a file header (similar to the "FF FF" header in a binary loaded file) which identifies the file to MAC/65 as a tokenized source file. MAC/65 won't load the file if this two-byte header isn't present.

The next two bytes are the total number of bytes in the file in LSB/MSB format minus the 2 header bytes and 2 byte-count-bytes. The formula to find the number of bytes in the file would be:

(((Sector count-1)*125)+number of bytes in last sector)-4

You subtract the 1 from the sector count because the last sector usually isn't full and you add the bytes from that sector in the next step of the formula. If your file is in double density, you would substitute 253 for the 125.
So if you had a 59 sector file and overwrote it with a nine sector file, you would start with 50 sectors (the other nine have been destroyed by the over-write). Now subtract 1 (for the last sector), and multiply the result by 125 (or 253 if double density). Now look at the last byte in the last sector of what used to be your file (sector links will have been preserved starting at the first sector after what was overwritten). The value in this byte is the number of bytes used by your program in that sector. Add this value to the total you got before and then subtract 4 (for the header bytes). The result is the total number of bytes in what's left of your file. You can now insert this value (in hex LSB/MSB format) in the third and fourth bytes of the first remaining sector of your file.

Dos always uses the last three bytes of a sector (whether single or double density) to keep track of what the next sector in the file is and also the number of bytes in the sector. The last byte of a sector contains, in hex, the number of bytes the file used in that sector. This will always be 125 ($7D) or 253 ($FD) except for the last sector of a file which may or may not use the full 125 (or 253) bytes of the sector.

The next two bytes are the actual beginning of your program and make up the line number, in hex-LSB/MSB format, of the first line of your program.

The next byte is the statement byte count. Not the actual count of bytes in a statement if you were looking at a listing of your program, but the count of how many bytes MAC/65 used to save that statement to disk, in tokenized form. Counting the bytes in a statement begins with the first byte after the byte that contains the statement byte count (the byte we're talking about),and continues to and includes the next statement byte count you encounter. So, if you know you had numbered your program by tens (i.e. 10 20 30 40 etc.) you can find the two bytes which contain the program line number, and you know the next byte following that is the one that contains the statement byte count. Now look for the next successive line number you think you used, and you can count the number of bytes for that statement. In this way, you can unscramble what will almost assuredly be the scrambled first portion of your program. It is very unlikely that the part of your program remaining after the overwrite starts at the beginning of a statement. And besides, you have to insert the two byte header and also the two bytes which make up the byte count of the file.

By using this counting method, you can find where each statement begins
and thus have your program start exactly where it should on the disk,
as far as the byte count goes. If the first statement of your program
doesn't begin exactly at the sixth byte of the file, you will be able
to load it into MAC/65 but part if not all of the file will be
scrambled and most likely MAC/65 wont let you do any editing to it.

Responding to a question from Stephen Lesniewski about how to copy 8-bit Atari programs to an IBM system to "archive" them, I think Jack Pettrey may have had the best answer...

If the concern is data integrity on old floppy disks, it might be FAR simpler to just DISKCOM the entire disks (DISKCOM is a utility which will turn an entire disk into an Atari DOS file, allowing later expansion back into an *exact* image of the original disk), and copy the resulting .DCM files onto new Atari formatted disks.

This would save file space on the IBM system, and avoid the hassles of transferring the files one by one to that IBM system. The .DCM files could be copied any number of times to other Atari disks before being eventually "unDISKCOMMed" back to their original states...

This raises an interesting question... many of *my* 8-bit disks are getting to be 8 or 9 years old... a lot of the disk manufacturers' data on "archival storage" on magnetic media is the result of "projections", not true "in the field" experience, since floppy disk systems have only been available for the last 10 years or so...

Are we justified in being concerned about the integrity of data stored on disks for almost a decade..?

Stephen has asked a very good question... something us "old-timers" may have to face as the 8-bit Atari computer enters its second decade...

From: RCH@cup.portal.com
Message-ID: <15514@cup.portal.com>
Source record: 116136

BobR asks about whether we should worry about our Atari disks that are getting up there (relatively) in years. I think that the same principles that apply to other magnetic media would apply here: Properly stored media in correct temperature tolerances and environmental conditions (i.e. dust-free, magnetically neutral) should last indefinitely. Disks that are used every day, naturally, should be backed up. Wear & tear on a data disk is much less than on, say, cassette tape, but there *is* wear and tear.

What amazes *me* is the number of people I have found recently who do not back up commercial disks (in my opinion the lowest quality diskette available! :-) and run with only *one* copy of DOS. A guy who calls my BBS was down for a week until someone supplied him with a copy of SpartaDOS; he had accidentally formatted his only copy. *tsk* *tsk*

I think the integrity of data depends entirely on use & wear, and not "disk rot," whatever that may be! ;-)

Curt,

I currently have two hard drives hooked up to my 130XE (although I used to use a 256K 800XL). To accomplish this, I bought a 1Meg Multi I/O board from ICD, the MIO XE Adapter (which gives you the normal XL parallel bus and two cartridge slots), an Adaptek 4000a hard drive controller board, a PC power supply, and the necessary cables. Prior to my purchase of SpartaDOS X I used SpartaDOS 3.2 which works extremely well with the hard drives. I have 2 20 meg drives (a Seagate ST225, and a MicroScience 20 meg drive). Since the maximum partition size is 16 megabytes, I have 4 partitions: 2 that are 10 megs, 1 of 15, and one of 5.

Most software that I've encountered will run from the hard drives (especially with the SpartaDOS X command 'X'). The only programs I can't run from the hard drives are those that boot from a floppy without a DOS, and protected programs that can't be copied to the hard drives.

If anyone would like more information as to how to go about building a hard drive system for an 8-bit, let me know and I'll be glad to assist you.

Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

Recently there was a burst of requests for addresses of archives
accessible to anonymous ftp.

In no particular order these are arpanet addresses of some places from which
I've gotten software or which maintain public archives for one of the
computers I use. This is the entire list so you'll have to cull atari
specific references yourself. I have connected to all of these at one time
or another, though, not recently for some of them. For those on
unix systems I'd remind you that sometimes there is a list of machine names
and their internet numbers in the file /etc/hosts.

An interesting non atari archive is expo.lcs.mit.edu. It has some 50 Mb of
bitmap pictures. They are in X11 format, but if someone were to write a
conversion routine, there would be plenty of stuff to use it with.

Roger Cornelius writes about retrieving source code from a file saved "on top of" his original file (a nightmare indeed!). He mentions that the methods might not be of use or interest to SpartaDOS users, but the idea is similar to a common practice Sparta prorgammers have access to.

ICD, the makers of SpartaDOS, have a "SpartaDOS Toolkit" that contains a wonderful sector editor. You can mark individual sectors to resave into another complete file, and even editor the disks' directory sectors and maps. Just thought I would post this in case anyone was interested. (The editor, called DISKRX.COM, will also work on non-Sparta disks, without some of the options, of course!)

1987. Re: Old Hardware and Software ... etc ...

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-10 04:22:11 UTC
From: RCH@cup.portal.com
Message-ID: <15611@cup.portal.com>
Source record: 116141

Al described his system; I am running a BBS on an unmodified 130XE with a 256K MIO board and 42 megs hard disk space (a tandon 252 10 meg and a 32 meg (don't remember brand), broken into two partitions. I run Carina 2.2 software and SpartaDOS 3.2.

The hard disk was one of the easiest elements of our system to set up. We got an Adaptec 4000A controller, plugged it and the drives into a 150W power supply and set it all up in a PC CPU case and stuck it on the floor. ICD makes both the DOS and MIO, so some really useful hard disk utilities are available.

1988. Questions about serial printers and 800 XL's

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-10 18:48:10 UTC
From: davise@yvax.byu.edu
Message-ID: <517davise@yvax.byu.edu>
Source record: 116142

I have a couple of questions:

1. With the 800XL do I need the serial-parallel adapter or can I just purchase a serial printer to hook up to the drive.

2. If I can use a serial printer, what is an inexpensive, yet semi-good quality dot-matrix printer.

I would appreciate in help at all.

Thank you.

Source record: 116144

The following is a message I posted to the 8-bit section of Fnet. I didn't feel like typing the whole thing over.

Conf : 8-BITTERS BALL
Msg# : 345 Lines: Extended Read: 2
Sent : Mar 11, 1989 at 1:25 AM
To : FLOPPY DISK
From : GARY DUZAN
Subj : Re: <333> SDX Paths

Those of you who have the SDX cartridge are probably aware of the PATH variable problem. In early versions, user programs had no access to the PATH variable. Now, the latest versions let you open files for read using the PATH variable, but essentially you have to say

OPEN #1,36,0,"D:QQQ"

instead of

OPEN #1,4,0,"D:QQQ"

This is fine for writing new programs, but doesn't help existing programs.

Solution: I have been going through some of my oft-used software with CODEBUSTER, fixing all the CIO open-disk-for-read commands to use #36 instead of #4. So far I have managed to get TEXTPRO and Determ (no handler) to read their system files through the PATH. Actually, I am typing this message from Determ right now. My default directory is >, DT.COM is in >BIN>, and LIST.BAT and PHONE.LST are both in >LIB>. All I had to do was type X DT (with the proper PATH variable set up) and I was ready to go. (Pretty quick too, off MIO RamDisk.)
Anyway, if anyone is interested in a copy of either program, let me know & I will Fmail you a copy. In case of any copyright problems, I will relinquish any reasonable rights to the original authors. I'm not sure of the official legal status of these packages, but I'm sure they are at least Shareware. Please treat them as the unmodified versions.
Disclaimer: Modifying someone elses code is tricky business. As far as I know, there should be no major problems caused by these modifications, but you should use them at your own risk.

Gary Duzan
Time Lord
Third Regeneration
Atari Enthusiast Extreme

A followup: I have just finished converting Kermit65 (no handler) as well. If you would be interested in these converted programs, let me know and maybe we can work something out. Also, if you have a favorite [generic free-type] piece of software that you would like to have use SDX PATHs, let me know.

Does anyone have a -good- basic compiler they might be interested in selling?
A nominal amount of speed, and compatability with either Atari, or basic XL
would certainly be a plus.

Thanks

>
There have been two compilers for Atari BASIC which I know of. One was the
ABC compiler, and the other name escapes my memory at this time.

The problem with these compilers is that the speed of your program will only
increase marginally, and the file size will increase substantially for all the
"Runtime" packages needed for screen drawing, math, etc.

I think if you need speed, but like the interactive style of basic, I'd take
a look at ACTION!, which was supposedly the fastest 8-bit language ever
developed. It was put out by OSS on a supercartridge, just like BASIC XL.
However, I remember a disk version of ACTION that someone cracked. (of
course I never had it, wink wink).

But I guess if you don't care about size or speed and you just need
something to run from DOS, look for the ABC compiler.

I believe the other compiler you're thinking of is the MMG BASIC
Compiler. According to the advertising I remember, it was supposedly
"better than any other compiler available for the Atari", but you could
probably take that with a grain of salt. There was also a product issued
that was a collection of MAC/65 macros with names corresponding to Atari
BASIC commands. (It's name, of course, escapes me. :-) You would run the
Atari BASIC (in LISTed form, presumably) through MAC/65 with these macros,
and you'd get a stand-alone ML program. I would imagine this ML program
would be quite effecient, since it wouldn't require any run-time code.

1996. Re: Questions about serial printers and 800 XL's

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-14 03:56:15 UTC
From: Bob_BobR_Retelle@cup.portal.com
Message-ID: <15811@cup.portal.com>
Source record: 116150

Evan Davis asked about using serial printers with the 800XL..

The Atari serial port, the "SIO Bus" is a proprietary I/O setup.. the ONLY printers which will work directly with an 8-bit Atari are those sold by Atari itself.. (a few other manufacturers used to make "direct connect" printers, but it may be pretty hard to find one now..)

To use any "standard" printer, you'll need some kind of interface..
The Atari 850 interface is a good unit, although sometimes hard to find..
it should cost around $99 (or less).

The P:R: connection from ICD is also very good, and costs somewhat less..

If you don't already own a printer, I'd recommend staying away from a serial printer, as the "standard" has become the "Centronics parallel interface." If you ever want to use the printer on another computer, it will be far easier with a parallel printer. (Another consideration is the software you'll be using.. very little software on the 8-bit Atari will direct printed output to the R: serial port. You may find it difficult or impossible to use a serial printer with your software.)

As for recommendations, stay with "Epson compatibility".. all too often you'll read desparate pleas for a printer driver for a "Yamaguchi 1093Xdi".. (or whatever), which no one supports..

Either a low cost Epson or a Panasonic should serve well, and even the lower models come with far more features than my venerable old Epson MX-80 did at twice the price..!

Todd Young asked about obtaining a BASIC compiler..

Have you tried the TurboBASIC language and compiler..?

It was written by the same programmer who did GFA BASIC for the Atari ST, and best of all, it's available for free.. commercial info services have it, and many local Atari BBSs and user groups should list it also..

It's upwardly compatible with Atari BASIC, and requires at least an XL..

It doesn't create standalone .OBJ files though, as commercial compilers like the DataSoft BASIC Compiler did..

1998. Re: Info-Atari8 Digest V89 #8 (1027 Problem)

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-14 16:51:41 UTC
From: Robert_J._Nash.WBST139@XEROX.COM
Message-ID: <890314-094547-1090@Xerox>
Source record: 116152

The answer to the garbled 1027 print output is best captured in two time-worn mottos:
* USE IT OR LOSE IT
* YOU GOTTA KNOW WHERE YOUR HEAD IS AT

If you watch the 1027 print head in action, you'll notice that doggedly zips hard left before printing a line. As explained in the 1027 owner's guide, the print head uses this hard left "home" position to align itself. The manual glibly assumes that garbled output can be eliminated by merely turning the printer on and off, since the printhead seeks the hard left position on startup. However, if you haven't used the printer in some time, or if you've let dust accumulate on the printer , then it's likely that the printhead won't slide smoothly to its "home" position. The cure is to take the lubricating oil provided with the printer, and lubricate the plastic drive gears of the printhead. Also make sure that the carriage rod (on which the printhead spins and slides) is free of dust and grime, and though not suggested by Atari, a touch of lube on this rod might also be helpful. Finally, make sure that there are no compacted dust balls on the left hand side of the print head --- the print head really needs to travel full left for a successful sensing of "home" --- even a small "spacer" of dust will turn the 1027 into a cryptographic printer.

Finally, one more bit of 1027 "news you can use" --- don't put up with faint printing; ink the print roller with ink sold for rubber stamps.

Mike,

I'm very interested in the collection of Mac/65 macros that resemble Atari BASIC commands. I would love more information about them, that is, if you have any. I have had experience with the MMG Compiler you spoke of, and had little trouble compiling many BASIC programs. The object files were rather large, but ran much more quickly than the BASIC version. I wish I had it now (a friend of mine showed it to me a LONG time ago). oh well.

I vaguely remember the other one... I think it was sold by Datasoft?
There's also a public domain basic compiler that based on Turbo Basic
(the PD souped up BASIC by Frank Ostrowski). I have a copy of this at
home. Unfortunately, home is 300 miles away, I won't be returning there
'til April, and I won't have net access from then through the summer. And
I never got around to testing it out. There were apparently some
problems in running it... I'm not sure how reliable it is, but check with
one of the PD software sources; they may have it, and if you can get it
for $5, you can't go too wrong...

I have used three different basic compilers, including the ABC compiler and Turbo. The turbo compiler is by far the best. It runs the standard atari basic, isn't limited to only integer numbers, and has extra commands not in Atari basic. A really nice program. It is also public domain (Free). The documentation is also a text file that can be sent along with the program. One catch, the compiler was written in Germany and the commands are in German. I revised my copy so the commands are in English, but the responses are still in German. (J/N vs Y/N) Tough, but most technical people can handle it. Let me know if you would like a copy.

Re: ZMAG #147

Noooooooooooooooo!!!!!!!!!!

Go to 40 columns if you must, but please don't include ATASCII control characters. ZMAG is relayed through a good number of systems that only support ASCII. Also, such an action would completely preclude printing them out. Personally, I prefer the 80 column format because I can either view it online with an 80-column terminal program (usually Kermit65) or print it out.

Gary Duzan

2007. Atari 8-bit System for sale

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-15 22:17:48 UTC
From: ajy2208@ultb.UUCP
Message-ID: <448@ultb.UUCP>
Source record: 115961
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st,wny.general,misc.forsale,ny.general

I've got the following system for sale due to the fact that I need money
for school. I would like to sell the system as a whole, as it might take
me a while to sell the entire system as individual pieces. Anyway,
everything works really well together! Here's the system:

Items
==========
Atari 130XE Computer, 128K RAM & Rev. C BASIC built in
ICD Multi Input/Output board
- RS232 (modem) port
- Centronics (printer) port
- SCSI/SASI (hard drive) port
- Firmware, and Printer Spooler
- 1 MEG RAM (fantastic Ramdisk!!!)
XE Adaptor for MIO (necessary to use MIO with XE)
Adaptec 4000A Hard Drive Controller Card
Seagate ST225 20 Meg hard drive
Microscience 20 Meg hard drive
Indus GT Double Density disk drive
Atari 1050 w/US Doubler (Double Density)
XEP80 80 column board (also has printer port)
R-Time 8 battery clock cartridge
SpartaDOS X Cartridge
Assembler Editor Cart
PC Power supply (150 watts) for the 2 hard drives & Adaptec
XT Case (two hard drives, Adaptec, MIO, & Power supply all fit here!)
Magnavox 80 column Monochrome Monitor (works great with XEP80)
100 Disks in 3 Alsop disk cases (including)
Hacker
Archon II: Adept
Omnitrend's Universe
Alternate Reality: The Dungeon
Spy Vs. Spy
Carina II BBS Software
20 Original Antic disks, in 2 plastic disk cases
Cables (HD cables, RS232 [modem] cable, etc.)
Power Strip
==========

I am willing to part with this system for a mere $1500. A lot of my time
and money (well over $2000) went into putting this system together.
The hard drives and the 1 MEG MIO board alone would cost nearly $1000 today
new! (each drive is roughly $200, and ICD sells the MIO for $450)

I've got all the cables and power supplies needed to hook everything together. The two hard drives have a TON of PD software on them, as I used to run a Bulletin Board System. I also have a lot of original software on the 100 or so disks mentioned above.

If you are looking to run a BBS, this is a great way to start. I ran Carina II and in my opinion it is better than any ST BBS software that has come out yet (including FoReM).

With a second monitor (or b/w TV) you can generate two entirely different displays by using the XEP80 and SpartaDOS X. I'll be glad to assist the person who purchases the system in setting it up, and if he/she is local, can do so in person. If you're not local to me, I'm going to have fun mailing all this!!

Please contact me at 716-475-4088 weeknights or weekends if you are interested in purchasing this system. Or, you can reach me at:

ajy2208@ritvax.bitnet - Bitnet
ajy2208@ultb.rit.edu - Usenet

The other BASIC compiler Matt Walsh remembered was the DataSoft BASIC Compiler... it had its quirks (like requiring ALL Data Statements to be at the END of the program), but the resulting code WAS quite fast, especially if you chose the INTEGER compile option (if you needed floating point math, you could compile under that option, but the speed suffered)..

I do agree though, that for sheer speed (almost as fast as 6502 assembly code), the ACTION language was the winner..

For ease of programming, and speed of development though, the BASIC compilers couldn't be beat...

skybridge.scl.cwru.edu was down for over a week.
We switched to VMS for a while &-(and then we grew some bugs %-(
Well we are up again. If mail bounced back, try to send it again
maybe it'll work this time. I'm looking forward to hearing from
you.

Thanx,
Gil Yehuda

A FREILICHE PURIM

2011. MONTEZUMA'S, ASSYLUM, PITFALL II and OMNITRENDS UNIVERSE

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-17 15:09:18 UTC
From: walshm@sun.soe!clutx.clarkson.edu
Message-ID: <2684@sun.soe.clarkson.edu>
Source record: 115965

Since noone else talks about the old 8-bit games, I guess I'll have to do
it. Yes I know there is a newsgroup for computer games, but I prefer to
interact with fellow Atari users.

Has anyone else ever won on PITFALL II? When I say win, I don't mean getting
the gorilla. I mean completing the section following the gorilla where the
"Pitfall Harry's only hope is to find the man, the pot, the flute, and the
magic rope". I ask because this feat took me most of a day to find
all these items and finally ascend to the top.

How about MONTEZUMA'S revenge. I mean the version put out by UTOPIA software,
before Parker Bros. raped it into a cartridge version for every computer made.
If you did well, you got the torch, and came to a HUGE man, at least 6 times
your heigth, who stamps and shakes the floor every few seconds. I could
never get much farther.

I am also intersted in finding out how many people took an interest and played
UNIVERSE. My version never worked completely, but what I saw looked like
STARFLIGHT for the IBM. I heard there was even a BBS for Universe players.
Was this a really good game? Should I try to find it again with docs?

Last but not least. Did anyone ever have success with ASSYLUM? This game
was your typical two word parser adventure game, except it featured a
3-d view of the room and hallways around you. However, the halls formed
a maze and the game was very difficult to map AND navigate. I was able
to dress up like alfred Hitchcock and get the movie camera and guard outfit,
and re-wire the fuse box, but I never got to the catapult, Dr. 'Bones' McCoy,
or to get the phone to work. How about anyone else.

Let me know if any of you have had better success than I, or comments.

I really liked Universe at first, but _only_ with two disk drives. This is a
five disk game, and with one drive the swapping is worse than ridiculous.
Also, the game is slow. After awhile, the novelty of descending to a starport
wears off. I found a bug in the game that allowed me to become a millionaire,
so I bought the best stuff and flew all over the galaxy. All this was fun
for a bit, but the object is to get this space booster, and I never did find
it.

The manual is large (100 (?) pages) and well done. When I had the game it was
expensive, but not copy-protected.

Has anybody completed the game? I'm pretty curious as to what happens in the
end.

Message-ID: <8903172225.AA26233@ucbvax.Berkeley.EDU>
Source record: 115967

I have one last question about the spartados x cart. In the
manual, it states that the computer can be rebooted with the cart.
dissabled if you give the command 'COLD/N'. When I do this, the
disk drive runs for a few seconds, and then the message 'Directory
not found' pops up on the screen. It does this with any disk I put
in the drive (some have directories, and some are boot-load disks
that have no directory).
On an unrelated note, could anyone give me the correct parameters
for the xio command #36 (set baud rate/parity/wordsize for the
rs232 interface)? All of the doccumentation that came with the
drivers I have (they were included with the r-verter interface) just
refer me to the atari 850 manual (not good advice, since I would not
have baught an r-verter if I had an 850...)
thanks for any help,
Raymond Courtois

From: RCH@cup.portal.com
Message-ID: <15941@cup.portal.com>
Source record: 115968

I downloaded the MMG basic compiler from a BBS in Atlanta last night,
and played with it a little before going to bed. If you want it, it
is in a DISKCOMMed file on my BBS, Freestyle, at 404/546-8256 (3/12, 24hr).

The program boots as an AUTORUN.SYS, and was DISKCOMMed with 2.0, so I will
have to play with it to see if it will run under Sparta. The program's
copyright is 1984 so I am not really hopeful! :-)

I believe the comapny was Special Software Systems, but don't hold me to that;
it was reallllllly late! From what I understand, though, MMG was released
into the public domain.

Program operation is simple: you give it the name of a saved BASIC files,
the name of the file to compile into, and whether it needs INTEGER or
FLOATING POINT math. Then it whizzes, whirs, makes several "passes" and
gives you a file roughly three times the size of the BASIC file. The .exe
file seems to perform fine, though I will have to try it with some math-
intensive stuff to see any appreciable speed increase.

I will play with it some more and let you know. In the meantime, give me
a call, and try it out yourself. (File should be called MMGCOMP.DSK or
something like that. Type GO ATARI at the section prompt, then either
DIRECTORY or BROWSE.)

Well, there needs to be a space in it: "COLD /N". I don't know what the
"directory not found" message is about. The screen should go blank & the
familiar boot procedure should begin. Remember to hold down OPTION to
disable internal BASIC if desired.

I don't have my manuals with me at the moment, but if you don't get a
reply, send me mail. Also, the codes are listed in the original "Your
Atari Computer" if you have a copy around.

Ignore my previous question about "with what do I unCompress?" I found a 'man' page about 'compress' on a Unix system, and did it there.

UNFORTUNATELY... The program you posted, Ken, turns out to be an IBM-PC program to read ATARI disks, NOT the other way around as I took your SUBJ: line to mean.

Therefore, I explicitly pose the converse question: does there exist a program to let an Atari with true double density (say, the US Doubler chip in a 1050 drive) read IBM-PC disks? That was what I thought the promised program purported to do, and only found out the opposite after going through quite a bit of work to extract it...

(And, beyond that, are you sure the program is meant for 5 1/4" rather than 3 1/2" floppies? I'll be explicit, again, and add to my above question the qualification that by "...IBM PC disks on the Atari..." I mean 5 1/4" floppies.)

Sigh...

About the MMG Basic Compiler...I haven't used it in several years (I use TurboBasic if anything anymore), but from what I recall, I had experienced some problems with it. *MOST* of the time compiled Basic programs worked just fine. It seems to me that I had a lot of trouble with programs that did extensive graphics though (lots of PLOT's and DRAWTO's)...the compiled version would either do nothing, or would draw the *wrong* stuff! Just wondering since the discussion came up, but is it just me, or was this a problem everyone had with it? In either case, for programs that did little graphics, or were all GRAPHICS 0, the MMG compiler worked like a charm.

I have before me Atari's "850 Interface Module Technical Manual" -- which,
believe it or not, documents more than you could ever possibly want to know
about that beast, and which CAME WITH the 850 when I bought it back in '82.
I've never seen anyone else with a copy of it, even among my friends who
also have 850's. I guess I "lucked out," as my mother would say...

The writeup on the XIO 36 command is a good two and a half pages of small
type, but that includes a lot of stuff we all already know (or at least,
work with enough to know "intuitively") -- what "baud" means, and so on...

Suitably edited, then, here's the scoop:

The CONFIGURE BAUD RATE command allows you to set the Baud rate, "word"
size, number of stop bits to transmit, and enable or disable checking of
DSR, CTS, and CRX. The command may be issued through an open IOCB to the
RS-232-C SERIAL INTERFACE port, or through an IOCB which isn't being used.
If you have opened an IOCB to the port you are configuring, you must use
that IOCB. You cannot configure any port if a Concurrent Mode I/O operation
is active.

The CONFIGURE BAUD RATE command looks like this in BASIC:

XIO 36,#iocb,aux1,aux2,"Rn:"

... the IOCB should either be open to the port you are configuring, or should
not be open at all. No Concurrent Mode I/O should be active when you issue
this command.

Aux1 ... specifies the Baud rate, "word" size, and number of stop bits...
For each of these, pick a number from tables B-1, B-2, and B-3 (see below -
CFC), then add the nummbers together to form Aux1.

Aux2 ... specifies whether or not the Interface Module should check Data Set
Ready (DSR), Clear To send (CTS), and/or Carrier Detect (CRX) when a Block
Mode output or START CONCURRENT MODE I/O operation is performed. If you ask

to have the Interface Module check one or more of these, the interface module will return error status if the line check(s) is not ON. The error status is returned from the Block Mode output attempt or from the START CONCURRENT MODE I/O attempt. The condition of the line(s) being checked does not matter at the time you do the CONFIGURE BAUD RATE command to turn on the checking... See Table B-4 (below - CFC) for values of Aux2.

Note that the preset values of Aux1 and Aux2 ... are zero, corresponding to 300 baud, 8-bit words, one stop bit, and no checking of DSR, CTS, or CRX.

The configured parameters will stay as you set them until you either reset them or until you reboot the system (turn the power off and back on). The SYSTEM RESET key will not reset any of these parameters. (Remember, this is for the 850 -- may or may not hold for later devices that merely "emulate" it. Included "for completeness." -- CFC)

You may configure each... (serial) port independently.

If you specify 8-bit words, there are no restrictions on operation of the port. However, the following restrictions apply to 7-, 6-, and 5-bit words:

* Full-duplex is not allowed
* Half-duplex input can be in Concurrent Mode I/O only
* Half-duplex output can be in Block Mode only
* Input and output can be only 300 Baud or less

(The implication is that today's modem communications are all done with 8-bit words; and you are using Concurrent Mode I/O for all such communications as well, if it wasn't clear... - CFC)

(more stuff on 7-, 6-, and 5-bit words, deleted. Do you want it? - CFC)

(more on checking DSR etc... want that? - CFC)

Okay, enough of that; that should cover what you need. The tables of values from Appendix B are reproduced below. Tables B-1, B-2, and B-3 list values (really "bit settings," but they don't tell you that) to be "added together" (or OR'ed into the bit mask) to form Aux1. Table B-4 lists values for Aux2. You should be able to easily determine the specific Bit Mask functions by examining these tables...

B-1: Baud Rate Specifiers to add to Aux1:

ADD BAUD RATE (bits per second)

0 300
1 45.5 (for Baudot teletypes; usu. referred to as 60 words/min)
2 50 (" " " ; " " " " 67 words/min)
3 56.875 (" " " ; " " " " 75 " / ")
4 75 (sometimes for ASCII, sometimes for 5-bit RTTY. 100 WPM)
5 110
6 134.5 (used by IBM systems) (??? -- CFC)

7 150
8 300
9 600
10 1200
11 1800
12 2400
13 4800
14 9600
15 9600

B-2: Word Size Specifiers to add to Aux1:

ADD WORD SIZE (bits)

0 8
16 7
32 6
48 5

B-3: Specifier for Two Stop Bits to add to Aux1:

ADD STOP BITS SENT WITH EACH WORD

0 1
128 2

B-4: Aux2 Specifications to check DSR, CTS, CRX:

ADD TO MONITOR

0 None
1 CRX
2 CTS
3 CTS,CRX
4 DSR
5 DSR,CRX
6 DSR,CTS
7 DSR,CTS,CRX

Th-th-th-that's all, folks!

Enjoy.

The 'game select' screen? How do you do that? I haven't heard
of that fun little room.
Also, I would like to put out a thought for most programmers.
Has anyone else realized that Atari has only made ONE videogame cartridge
for the 2600 that has a fatal bug in it. Considering the amount of
software revisions and bug fixes that I see for computers (MACs, SUNs, ...),
I find that to be a very good record. Yes, the software was smaller and
easier (more fun) to test, But it still means something!!
Oh, for those who don't know which cartridge, try Warlords in 3 player
mode. It will occasionally not give the ball back to continue after a point
is scored.

I don't think a version of Adventure was ever put out on the 8-bit, but there was an interesting game called Castle Hexagon that I enjoyed quite a bit. It entailed going through a castle, picking up objects and putting them in their proper rooms. Although I've looked almost everywheres, I really can't seem to find a copy of it. It was a PD game.

I'm also a VCS freak, but never played Adventure. Maybe I should look around for it.

There was a game for the 8-bit VERY MUCH like the adventure VCS
cartridge-- "The Holy Grail" (published by the (late) APX; Atari's "home-grown"
division). THG had _many_ rooms to explore, "secret" rooms and passages, and
was a kick for us Monty Python fanatics...
However, finding it (of course) will probably be difficult...

How about using one of the many communication programs available which
usees X-modem protocol. One good one is 850-express, another older one is Chameleon.

You can then go computer-computer using only the RS232 port on the apple
and your serial connection on the 850 or equivalent. When you make your cable
watch pin 8. Some programs (850 express for one) requires this lead be held
high, while some others dont.

2031. Got those 48K blues...

Newsgroup: comp.sys.atari.8bit

From: smb@cs.purdue.EDU
Message-ID: <6289@medusa.cs.purdue.edu>
Source record: 115985

I have an Atari 800 (the old kind) and although I want to get a bigger, newer machine, I am confined by my budget to wait on that. In the interim, I want to try to expand the memory of this machine beyond the current 48k. I know there are many people who have done so and written instructions on how to do it and I hope that one of you out there has one or more of these "How-to" documents online and will send it to me. Please let me know about your experiences with any of these expansions even if you can't send me information on how to do the expansion. Also, please include any compatability information and reference any programs that may be needed to use the extra memory.

Thanks,
Scott Ballew

From: clf3678@ultb.UUCP
Message-ID: <482@ultb.UUCP>
Source record: 115988

Yes, a number of memory upgrades are available for the 800. However, finding one will be difficult. Axlon once made a number of upgrades, and you can make them yourself by modifying a 16k board. However, you will find that your upgrade won't really be compatible with those for the XL/XE machines. What I mean is, you can't get a 64k/128k program meant for newer machines and expect it to run on the 800. I might be wrong about this, but this is my experience with it.

=cf=

2035. Re: 64K for Atari 400.

Newsgroup: comp.sys.atari.8bit

Message-ID: <483@ultb.UUCP>
Source record: 115989

I don't believe that you can expand a 400 to 64k. The highest it will go (the highest I've ever heard it can go) is 48k. I believe Axlon made a board that did this, and POSSIBLY Atari had one at one time. If you want 64k, you will have to get an XL/XE.

2036. Re: Wanted - Kermit for Atari 800 (or something like it)

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-22 22:53:58 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <6278@bsu-cs.UUCP>
Source record: 115996

I seem to have missed the original posting, but in article <1180@ncrcce.StPaul.
NCR.COM>, young@ncrcce.StPaul.NCR.COM (Todd Young) replies:

> How about using one of the many communication programs available which
> uses X-modem protocol. One good one is 850-express, another older one
> is Chameleon.

Those are fine if you can stand 'em -- but Chameleon's terminal emulation is
rather disappointing, and 850 Express! does none at all. In my experience that
is a very irritating tradeoff.

>
> You can then go computer-computer using only the RS232 port on the apple

Ah. If we're talking about an APPLE-to-Atari connection, perhaps terminal-
emulation isn't such a big issue.

Nonetheless, the implication that the original poster wanted to talk to an
existing Kermit on his Apple, says that only Kermit will do (he'd have to
get a matching XMODEM utility on the Apple, if he used Chameleon or
850 Express!).

Therefore, as I do every time this subject arises, I suggest John Dunning's
excellent "Kermit65," ported from the Commodore-64 and quite functional and
satisfying in all ways.

It performs not only Kermit file transfer, but also one of the best and most
versatile VT100 emulations I've ever seen on the 800 series.

Kermit65 can probably be obtained from ANY NUMBER of people right here on this
newsgroup... I'd try posting it myself but I need to minimize my use of
this account!

Upgrades to the old atari 8-bits are rather messy. A friend of mine
(Ron Bolling of UPGRADE Productions) does upgrades for just about every
one of the 8bit line. I have an 800 with 320k, but it is addressed
differently than any other upgrade i know of. There are many ways of
addressing ram in 8bit atari's. Exactly how do you want it to be addressed?
If you want compatability with the XL/XE computers, then you need to be able
to address memory underneath the operating system via the pia address.
Mosaic memory systems used to produce an upgrade that did that. In addition
to being able to address all of your memory as RAM (64k), there are various
ways of exceeding this by using memory banking. The 130XE (and compatables)
use 16k banks in memory from $4000 to $7FFF. The bank selection is also
done through pia port B. The Axalon system banks in the same place, but
is banked through a register located at $CFFF. The Mosaic Ramdisk banks
only in 4k banks in memory locations $C000 - $CFFF, and is selected by
writing to memory locations $FFC0 -$FFE0.
My 800's system is completely different. We affectionately call it the
64k+. The operating system memory as well as memory (cartridge) protection
is enabled by a write only register somewhere in the unused I/O addresses.
The extra (RAMDISK) memory is banked in two locations. First in 4k Blocks
from $C000 to $CFFF, and then in 256 byte blocks from $D700 to $D7FF.
The upgrade provides for deselection as well as memory protection (simulated
ROM) for these memory locations. They are also banked via write only regs
in unused I/O memory locations ($D000-$D7FF). Ron also has a simular upgrade
for atari 400's, but there are a few things left out due to the archatecture
of the 400.
Ron has also come up with a complete memory system for XE's which gives
cartidge memory protection, operating system ramdisk support, and expanded
memory up to 2 meg. This is made possible by the addition of an extra PIA.
I have one of these, and let me say that its great!

I don't know much about getting the axalon/mosaic upgrades, but Ron still
does them. (A couple of months ago, he upgraded a 16k 400 to 52k for a

friend of mine.) I don't know about his current pricing though. If your intrested in finding out about any upgrade Ron does, just send me e-mail, and I'll try and find out.

Here's my problem...I'm currently fooling around with the Ace C Compiler, and using a Word Processor to write the source code. Everything would be fine, BUT my Word Processor(Speed Script) doesn't let me exit back to DOS so I can recompile my program. It's a real hassle to have to power down and power back up just to edit the source code. So the question is:

DOES ANYONE KNOW OF A (CHEAP) TEXT EDITOR I CAN USE FOR THIS PURPOSE?

I tried downloading one off of bitnet, but those bitnet files aren't to reliable(sp?)!!!! I've tried downloading six files and only on of them worked. Oh well that's anothor story in itself.....

Rob S.

P.S. Gary if you are reading this could you put me on your Z-Mag mailing list???!!!

A friend of mine has a 1megabyte 800 that he still insists on using solely because he did get the 1meg upgrade. While I don't remember who he bought it from, he did buy it less than a year ago. It is a single board, and it has a switch that will turn it on/off if the need ever arises.

As someone stated earlier, this RAM is not directly accessible by the computer. If I remember correctly, it can only be used as a RAMdisk. It is also compatible with AXLON memory boards.

If anyone would like more information, I'd be glad to fetch it for ya..

From article <1503@umbio.MIAMI.EDU>, by dnelson@umbio.MIAMI.EDU (Dru Nelson):
>
> Too all of you Atari 8 bit'ers... Keep the faith.
>
Thanks, Dru. We have been keeping the faith for a couple of years now hoping that Atari's push of the XE Game System would result in many new games and eventually more productive software. So far, Atari is the only company to release software in cartridge format. Another hope was that the popularity of the 8bit system in Europe would result in some good software for us here in the USA. So far, not much has come from that area either. Mostly PD software such as Turbo BASIC. If you have the capability to write some good software, go for it.

I read some news that was more discouraging than encouraging. In the Feb issue of Video Games and Computer Entertainment, there was a short blurb on Activision's Shanghai game and how it was available worldwide on 24 computer systems. One mentioned was the 'Atari XL/XE in Europe'. Why only in Europe? I'm going to write a letter letting them know how I feel about their narrow minded view :-) . All kidding aside though, I have written several letters to various third party software companies. I have gotten anywhere from no response to 'Atari doesn't make the 800 anymore'. No positive responses at all.

Speaking of PD software, why don't we start a list of the best of the PD software. I would like to know if there is some that I don't even know about let alone have a copy of. Off the top of my head, this is where I would start:

Daisy Dot II (soon to be III)
Turbo BASIC
CC8 C compiler (from Steve Kennedy)
Kermit 65

How about adding your favorite to the list. (I include Shareware in with PD, even though it is in our own best interest to support those developers who ask a donation)

2047. Atari Users Group Meeting

Newsgroup: comp.sys.atari.8bit
Date: 1989-03-24 23:07:35 UTC
From: c08_d102@jhunix.HCF.JHU.EDU
Message-ID: <1224@jhunix.HCF.JHU.EDU>
Source record: 116001
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

I've noticed a note in the latest Checkbits stating that the next
meeting would be Tuesday, March 28th, 8:00PM in Gilman 12. I should
warn everyone interested that I've not yet reserved this room, and I
don't know if Mark has taken care of that himself or not . . .

Personally, I would prefer to meet at a member's home again, as it's
a bit more comfortable to sit on a rug, even, than in a classroom for two
hours. Also, it's nice to see what's available for the machines first hand.
Unfortunately, my room is going to be painted, I've packed up my computer
for a couple of weeks, and the local spacio-temporal fractures have started
acting up again, so my place isn't a good idea. Anyone want to volunteer their
own room? (Cross your fingers, in two weeks I might have a) a real fridge,
b) a non-silly-putty sofa, c) a real kitchen table, and d) more room for the
computer equipment (not to mention people). Then my place will be fine.
I should have started demanding all this sooner...)

And now, for a progress report.

o No progress toward getting a model constitution to modify.
(Eric, are you out there? I know Joe is using your
account, but do you ever use it yourself?)
o No progress toward becoming a real SAC group
(but then, it's Spring Break).
o Some progress toward a software library.
I spent a few days going over my archives of software and have
made some sense out of it. Now, I need a disk cataloging program
to make a list of what I have. I'd appreciate other members sorting
through their own public domain software and cataloging it, too,
so we can cut down on time spent on ftp'ing and listserv'ing
(believe me, you'll appreciate this someday...).

If this all seems a bit discouraging, well, it's only been a week.
The main purpose of the above was to get some action going vis-a-vis
cataloging your software. Do it! I found the most amazing things
lying around on my disks, myself . . .

On a side note, I like the way the ATARINET server at UH-INFO@UHUPVM1
hasn't been updated since last Halloween.

And now, a quick answer: Yes
BTW, have you used your trackball a lot? I was using one as a mouse. It worked OK, but is not really a one-hand device; I found it hard to push the button with the same hand. Also, it was starting to get jammed sometimes; you would have to wiggle it a little to get past the rough? part.

I now use the Commodore mouse. It has a proportional mode (with analog outputs; apparently, it can be read using the Commodore pot reading circuit, but for some reason can't be read through the Atari. I tried both normal and fast-pot-scan modes.) and joystick-simulator modes. I converted my software to track the joystick mode. (In simulated joystick mode, the second mouse button is read through a pot input.)

Hello,

Can anyone shed any light on the reference in compute's computer viruses book to the existence of a link virus for 8 bit Atari computers. The book refers to a warning from Bill Pike (Portland Atari club president) about such a virus.

I am in the process of compiling a list of known computer viruses for the virus-l mailing list and would be interested in details of any known Atari viruses, preferably including:

1. Symptoms observed (especially damaging)
2. Virus type (boot sector, link, transient or resident)
3. Geographical distribution and reported infections
4. Available disinfection software

Thanks very much.

I seem to have the same problem. A couple of people did get thru to me,
and I can't even get a response to them.

I compressed Turbo Basic, the compiler, the runtime, and all of the docs
together into one 370 sector file called TURBOBAS. They were compressed
using ARC. That file was put onto a local BBS at 707 539-8889. You can
log onto this BBS using a password of ANON and the last 4 digits of your
telephone number being 8889. ARCX which will uncompress these files is
also on the BBS. For a complete listing of available files, download a
copy of README. If you have problems give me a call at 707 539-4991.
This is my personal phone number, so please do not use your computer to
call.
If you log onto this BBS, leave Bill (The sysop) a message of who
you are, and please thank him for letting me use his bbs like this.
Good Luck with Turbo

Nick DiMasi asks:

>> I do agree though, that for sheer speed (almost as fast as 6502 assembly
>> code), the ACTION language was the winner..
>> ......
>>
>> BobR

>Why did you write this in the past tense? Is there now a compiler that
>produces faster object code than ACTION! ? (Not that I would want it,
>I don't even have much time to write programs anymore, although I'm working
>on it...)

Sorry.. just being fatalistic (or realistic, perhaps) about the idea of
doing ANY coding on a 6502 machine anymore..

No, I doubt that ACTION will ever be surpassed by anything other than pure
assembly code.. I remember when OSS visited the local user group (MACE),
and put on a terrific demo of the *new* ACTION! language cartridge...
blew the socks off everyone in the place...!

And, as far as I know, there was *nothing* that even came close, for any
other 6502 based computer...

I assume that you are in the market for an Atari 8 bit? If so, why, and how much can you spend. If you have enough money for a new computer, I would suggest a Mac. And if you can't afford that, I'd go Atari ST or Amiga, whichever is cheaper for you.

>viruses....

While I missed that reference, I will mention that due to the "patch-work"
nature of Atari hardware, operating systems, memory and peripheral mods and
a whole host of other reasons, viruses for the Atari would have to be
pretty machine specific. Most all Atari peripherals are "intelligent,"
meaning they contain their own controllers, chips and the like.

Just thought I would add this.....

> Hi all! Just a quick question...does the old Atari Trackball
> work as an upside-down mouse? (ie - the new desktop OS's, GOE
> and Diamond will work with the ST mouse. Am I correct in
> assuming that they'd also work with the trackball?)

The Atari (and presumably any other compatible) Trakball controllers (there were at least 2 different Atari trakballs) do _not_ work exactly like an ST mouse. I tried the old GOE demo disk with an ST mouse and it worked as it was supposed to. But with my (CX22 I think is the model number) trakball, the cursor moves to the upper left corner of the screen and is stuck there (in trakball mode), or moves, "flakily," 90 (or is it 270?) degrees from the intended direction (in joystick mode). As far as Diamond goes, I can't say. (At the last meeting of my users' group, we saw Diamond respond to an ST mouse, but we couldn't get it to do anything - we had no manual - and I didn't have my trakball with me anyway.)

However, I have (at home, not here) some instructions on modifying an Atari trakball (at least for the type I have, I may have saved the other instructns.) to act like an ST mouse. I got them from DELPHI, which means they must be all over the place since (except for stuff from ANALOG magazine) DELPHI is about the last place to get anything (if it gets there at all).

If you can't find these instructions on whatever BBSs and/or pay services you have access to, I will dig them out and (especially if I have them in a disk file) and mail or post them (depending on the level of interest here).

Disclaimer: I have not made any modification to my trakball. It is often all too easy to destroy a device while trying to modify it (although this is much more likely with the computer itself, I believe). Caveat Hackor.

Textpro is another excellent PD 8-bit program. It is an exceptional word processor that I have been using for some time on my hard drive system. There are some things I wish it did have though, such as 80 column support for the XEP80, and a dictionary (although I could live with an external dictionary program--anyone have a good one???). It would be nice if the program was a little faster in some operations, such as in sorting the directory and during search/replace operations. Oh yea, the only bug I've found in the program is if you have a directory that takes up more than the three columns allocated (when you hit Ctrl-m), the program locks-up. I continually run into this since I have lots of files on my hard drive (yes, I make extensive use of subdirectories too), and fortunately hitting RESET fixes the problem (and retains the document in memory).

One of the outstanding features of Textpro is the macro language built into it. I haven't used it too much (yet?) but it is very powerful and flexible. I'm sure someone else with more macro experience can speak more on this subject.

Enuf for now,

Buy a Mac over an ST or Amiga??? That's ridiculous. Besides, for several hundred dollars, you can emulate a Macintosh on an ST Rather well!! Plus the ST is less expensive than the Mac. The ST is a much nicer machine than the Mac. It has all the standard ports you'll ever need, 1, 2, or 4 megs of RAM built in, a 192K OS, great color and sound, MIDI built in, and much more..

>
>=cf=

Oh yes you can, but the 400 can only access 48K without bank switching.
I have a 400 at home (in the closet now - unused) with 64K and a variety
of BASIC (yecch) programs that use the extra 16K. Haven't used it in a
long time (since I got 800XL as a gift) but it requires poking a value
into some register telling the processor to access the other bank. There
were at one time several 64K upgrades for the 400, but none that I know of
now. installation of the upgrade board required soldering two jumpers on
the motherboard (yikes!) so it's not a trivial upgrade.

Hello.

I'm looking for 6502 source code for the handler for the Atari 850 interface module. There is a substitute handler that I downloaded from here (ATARIRS.UUE) but it's only the object code.

Also, are back issues of Zmag available somewhere? I only read a couple of them before they stopped being a part of comp.sys.atari.8-bit. And how can I get the new issues?

Source record: 116020

I just heard that Atari Corp. just sold their 6502 based computers and all their game systems to Coleco.

Can anyone verify or shoot down this rumor?

If it is true, I guess Atari finally wants to get rid of their "game machine" image. To me, the key word here is "image". Selling off the game systems and low end computers will NOT change their image.

The name Atari is synonymous with games. We all know that they also produce "real computers" but to the non-Atari computer owners, they are just toys. The only way to loose their image is a name change.

I hope that this rumor is untrue. The fact that I havent heard anything of the sort doesn't mean a thing, but my father is the presedent of a small but rumor consious Atari users group in Los Alamos, and at their meeting last friday nothing of that sort came out. If this rumor is true I think that the eight bit computers wont last long (look at the Adam and Colecovision), but will they anyway even if Atari holds on to it? My father has also tried to sell various programs in Antic and Analog, but has had three sales in the year or so he has been selling. (He has had at least 200, probably more, inquiries from 7 or 8 adds.)

Source record: 116022

I have an Atari 400 with a 16K memory board in it. I would like to
bring it up to 48K. Does anyone out there have instructions on how
I could make this modification myself? On the other hand, I have
the current catalog from Best Electronics (408-243-6950) which has
two 48K expansion options advertised on Pg. 4. Does anyone know
what the difference is between the -48K Expansion Kit (CB101052)-
and the -48K Atari Expansion Board (CO61553)- ?
I would prefer to do the mod. myself since I probably have
the spare IC's in my collection box at home and soldering irons
don't scare me but I may just order one of the items mentioned above.

(BTW - I got this as part of a package deal with some other stuff that
I just ->had to have<- and thought it would be fun to hack on.)

AdThanksVance for any info.

I __HIGHLY__ doubt the rumour about Coleco purchasing Atari's 8-bit machines is true. This rumour seems to have been an April fools joke posted first to BBSs and then uploaded to the net. The message indicated that Atari sold the 8-bit computer line to Coleco for $50,000. C'mon, that's ridiculous, it's certainly worth a LOT more than that!!! Anyway, the 'press release' as it was called was dated 04/01/89.

Source record: 116024

In an article whose header Portal doesn't pull into the reply, Jean Goulet writes:

> I'm looking for 6502 source code for the handler for the Atari 850
> interface module. [...]

If you haven't had any other responses to your query, write me e-mail at

Chris_F_Chiesa@cup.portal.com

and we can discuss this; I may be able to help.

The actual 6502 code that handles the 850 Interface Module is downloaded from the 850 itself at boot time, through a sequence of SIO commands that I've never seen documented but which I have investigated on my own. This approach seems capable of allowing a person to "fool" the 850 into sending the handler to the computer under the control of a debugger (DDT, nee Bug/65) whence it may be saved to disk, investigated in memory, single-stepped, etc. I haven't taken it this far myself, but it seems it ought to be fairly straightforward.

One concern is that this will NOT produce "source code." At the immediate level, of course, all one would have would be executable code -- but with proper tools that could at least be disassembled. If this is adequate to your needs, Jean, write me and we'll see if we can work something out. If not, best of luck finding the information you seek. (And, while you're at it, tell me more about this "other" handler you've obtained? I've never heard of it.)

Cordially,

Chris Chiesa

A question was raised about expanding an Atari 400 to 48K:

>I have an Atari 400 with a 16K memory board in it. I would like to
>bring it up to 48K. Does anyone out there have instructions on how
>I could make this modification myself? On the other hand, I have
>the current catalog from Best Electronics (408-243-6950) which has
>two 48K expansion options advertised on Pg. 4.

I used an Axlon 48K RAM board to expand my 400 years ago, and the installation was smooth and sweet, with no problems experienced at all. Because the 400 was not designed to address more than 16K directly at the RAM board socket, you needed to solder a small "template" pc board onto the bottom of the motherboard between the RAM socket and the cartridge socket to bring in the missing address lines, but that was a simple procedure. Once that was done, the 48K RAM board just plugged in and the upgrade was complete (FAR more easily done than upgrading an ST..!)

I'm not familiar with the part numbers mentioned in the BEST Electronics catalog, althouth the second one:

> -48K Atari Expansion Board (CO61553)-

sounds like an Atari part number. I was never aware that Atari Inc. had officially released a memory upgrade for the 400, but I imagine anything is possible.

The best thing might be to call BEST and see if anyone there can give any information about the upgrades.

One last bit of perspective.. the Axlon 48K RAM board I installed in my 400 cost virtually the same as the 512K expansion board that I installed in my 520ST a year ago... whew...

Attention Alternate Reality - The City players. Ever wonder about
the area bounded by the Arena, The Western Royal Walkway, and
North Main Street? If you've mapped the game out, it seems
reasonable that you should be able to find an entrance to that area,
right? Well guess what? There are more areas to explore in there!
That's right...at least 5 more buildings to enter reside in that
area. So where's the entrance to it you ask? Well, either accidentally
or on purpose the entrance was sealed off by the programmer (Philip
Price) or by Datasoft. Here's a short BASIC program to open up
that entrance for you!

What to do : type in this listing and save it. Make a backup copy
of Disk 2, Side 1 of the City. Load this program. Insert your
backup copy in drive 1 and RUN it. From now on when you boot up
the game using this new Disk 2, Side 1, you'll be able to enter
the above described area. Just *where* is the entrance exactly?
C'mon, this is an adventure game...do I have to give you all
the answers??? Find it yourself!

2079. April Fool's Joke from Happy Computers

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-04 03:02:58 UTC
From: charles@c3pe.UUCP
Message-ID: <6665@c3pe.UUCP>
Source record: 116033

Today I was pleased to find my new Happy 1050 Enhancement waiting for me when I got home from work, five weeks after sending in my order (with a personal check, which was said to induce a 3-week hold). Although the hardcopy documentation supplied doesn't cover the new features, in particular the MS-DOS read/write capability which I bought the unit for, a quick perusal of the Warp Speed Software disk revealed the utility and a description of its use. I'll try it out Real Soon Now.

But the real surprise came when I booted the "OSS DOS XL (Single Density) Now with BUG/65" disk which I ordered for "true double-density capability". I was anxious to assure myself that this was simply an old, inaccurate label on the floppy. But I was totally unprepared for the menu which appeared:

Atari DOS 3 Copyright 1983

Blah Blah
Blah Blah
Blah Blah

Error 8: Cannot write MEM.SAV

GAK!!! Needless to say, this menu does not agree with that described in the nice 200-page OSS DOS XL Reference Manual, but instead bears a striking resemblance to what I get after booting the floppy which came with my 1050 some years ago... right down to the output of the Files command to compare the directories on the two disks.

So, does anyone know what has happened here, or why? Perhaps someone put the wrong master diskette in their duplicator by accident? Or maybe an employee decided to pull an April Fool's prank?

Inquiring minds want to know...

Message-ID: <5375@cbnews.ATT.COM>
Source record: 116034

Folks, I'm the author of the CC8 compiler. I haven't done anything with the compiler for well over a year and have come to the conclusion that I'm never going to anything more with it--I just don't have the time anymore. So I'm looking for someone to pass the torch to. Is anyone out there interested in taking over the source for CC8? One important note: unless you have access to a VAX 11/7* running UNIX, you're probably going to face a sizeable, but not insurmountable, porting problem right off (mea culpa). I think I can briefly explain most of the other bizarreness in the source. Send e-mail if you're interested.

From: robby@vax1.acs.udel.EDU
Message-ID: <3241@udccvax1.acs.udel.EDU>
Source record: 116036

I'm not really into games that much, but I saw an ad for California Games which has four or five different games(surfing, skateboarding, I forgot the rest of them). Does anyone know if this game(s) is/are available for the Atari 8bits? If so, does anyone know where it can be purchased(at a reasonable rate)?

From: AMONSON@IDCSVAX.BITNET
Message-ID: <8904071504.AA22717@ucbvax.Berkeley.EDU>
Source record: 116037

I am looking for the UNARC utility for the Atari 8-bit computers. I have tried using long distance BBS's but the line noise in my area is too great. I also have tried finding someone in my area but no one has it. My local BBS's have a large number of arced files but not one of them have the UNARC util. for the Atari 8-bits. So if any one could tell me where I could buy it or if you have it upload it to me, I would really appreciate it.

>
>Cordially,
>
> Chris Chiesa

I too found out that the handler is in ROM in the 850. Thing is, I don't have an 850 (it's awfully tough to disassemble code that you don't have). Luckily if you use FTP and OPEN 36.8.0.46, and go to the 8-bit directory, you'll find ATARIRS.UUE, which you download and uudecode, and you get an ARC file, and then you deARC that, and you get the object code for the handler (apparently a debugged version). Naturally when you disassemble this you get no descriptive comments, and since the program probably uses all sorts of tricks, it would be very hard to understand. Hence my call for source code.

Now why would I want to understand this thing? The answer is that I was wondering how tough it would be to build the equivalent of an 850, or an R-verter (or both in fact).

This leads me to ask, if you open up the R-verter, what hardware do you see? My guess is that it's got chips for converting RS-232 signals to TTL signals (and vice-versa, using the MC1488 and MC1489). The problem with this guess is that one of these chips needs a +/- 12V supply, and that's a problem if your only voltage source is +5V (from the serial port; that *is* where the R-verter plugs in, right?). Does the R-verter have an external power supply? What is the maximum baud rate of the R-verter? Also, I once heard that there was already a public-domain version of the R-verter (a schematic at least), so if anyone has/knows of this, let me know.

Now I have a few questions regarding the 850:
- which serial port on the 850 do you connect a modem to? (1-4)

- which pins are used on the atari SIO cable, and which RS232 signal does each pin correspond to? The table below is waiting for the answer.
(I added a column for the R-verter in case it's different)

RS-232 signal	from 850 SIO port pin #	from R-verter SIO port pin #
TD (transmit data)	5?	5?
RD (receive data)	3?	3?
CD (carrier detect)	?	?
RTS (request to send)	?	?
CTR (clear to send)	?	?
DSR (data set ready)	?	?
DTR (data terminal ready)	?	?
SG (signal ground)	6?	6?

Once I get this info, I plan on using my unused 64K 400 (yes, they exist, contrary to a message from someone saying that you could only fit 48K in that machine; the 64K board was called the Mosaic 64K Ram Select) as the brains for the 850 emulation. That is, the modem will connect to my RS-232-to-TTL converter, and that will be connected to the 400's joystick port, and the 400's SIO port will be connected to the XE's SIO port. The 400 will appear to be the 850 as far as the XE is concerned. That way any software written for the 850 (i.e. virtually every terminal program) will run without any modification.

I'll have to write two programs to make it work: one to handle the RS-232-to-joystick port interface, and another to handle the joystick port/SIO port communication interface.

The first program will have to do serial-parallel conversion quickly enough to operate at 1200 bps. Timing will be critical too, so I plan on using interrupts triggered by POKEY's hardware timers. If you have any comments of the type 'it is impossible' then let me know. I figure it's possible because I think Supra/MPP has a 1200 bps modem that connects to the joystick ports, and one of the Volksmodems does that too.

The second program that'll be running on the 400 will be the one that sends all the right responses to the XE. I think that'll be the hard part. From what I can tell, I need to know the codes that are send out through SIO that do things like identify the device (R:), say how many bytes are coming, do a checksum, and differentiate between sending *text* to R:, and sending *commands* to R: (such as setting the baud rate or setting parity). If this information is already described briefly in a manual somewhere, it would certainly be a great help to have that transcribed in Email here.
Otherwise, I'll have to disassemble the 850 handler to find out.
Does anyone have documented source code for the 850 handler, or other modem handlers?

2085. 850 parity

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-06 20:07:40 UTC
From: young@ncrcce.StPaul.NCR.COM
Message-ID: <1224@ncrcce.StPaul.NCR.COM>
Source record: 116039

I don't recall who was asking about the 850 parity settings, but I finally found my 850 reference manual. Parity setting are done through XIO #38.

INPUT PARITY OPTIONS ADDED TO AUX1

0 INGNORE PARITY
4 CHECK FOR ODD PARITY - CLEAR PARITY BIT
8 CHECK FOR EVEN PARITY - CLEAR PARITY BIT
12 DO NOT CHECK PARITY BUT CLEAR PARITY BIT

OUTPUT PARITY OPTIONS ADDED TO AUX1

0 DO NOT CHANGE PARITY
1 SET OUTPUT PARITY TO ODD
2 SET OUTPUT PARITY TO EVEN
3 SET PARITY TO ONE

MISC -

64 APPEND LF AFTER CR

Good luck.

Action might be the fastest compiler, but it is clearly a waste for
anyone who wants to produce a useable program.

If you want *real* compiler, use Mac65.
```

Try Analog magazine for the 256K upgrade, the name of the company that
offers it is Newell, I think, don't quote me. They also make other upgrades for the Atari.

Well, I don't know about that. When I was doing development work
on the 8-bit Ataris, I switched from writing my pseudo-code from Basic-XL
to ACTION! since the speed was _a lot_ closer to the assembly speed it
would finally be in. I even wrote many of my conversion and editor programs
in ACTION!, and they were quite useable. Plus the enviorment, going from
source to the editor to running it was great.

> If you want *real* compiler, use Mac65.

I always like the AMAC (Atari Macro Assembler) since I think it
is a great shame to treat assembly like BASIC source with line numbers and
a BASIC-like editor. If only AMAC was as fast as Mac65 and less buggy. 8^)

Just some of my thoughts, but then you knew that. 8^)

2090. Parallel Printer interface

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-07 19:31:40 UTC
From: rbharding@orchid.waterloo.edu
Message-ID: <682@orchid.waterloo.edu>
Source record: 116044

I was wondering about how Atari printer interfaces, or the P: driver handle conversion of ATASCII to ASCII. It seems to me that if the ATASCII codes such as EOL (155, $9b) are universally converted to the ASCII codes, such as CR/LF (13,10 $0d$0a), then important things like dot-matrix graphics will be munged up. But if they aren't converted, then normal text won't print properly.

How is this resolved? My theory is the following:

- The P: handler will perform conversion of ATASCII to ASCII if the output command is PUT_RECORD. This command is line-oriented (a record is always terminated by an ATASCII EOL (155)).

- If the output command is a PUT_BYTES, the P: handler performs no conversion whatsoever, so graphics dumps will work correctly.

Am I reasonably close to the truth here? I need to know, since I am faced with the task of writing a P: driver for the parallel port I built for my old-style 800. Currently, I use a cludgy SpartaDOS program I whipped up:
PPRINT fname.ext

Thanks in advance.

In general, this is handled by the interface. ALL EOL's (155) are
translated into CR (13, or CR/LF (13/10), depending on the interface.) This
does, in fact, disallow code 155 in any bit-mapped output to the printer.
Generally, programs which send bit-mapped data to the printer are required to
check for a 155 and either report an error or send it varied slightly (more
likely the former.)

For a general solution, rewriting (or patching) the built-in P:
handler to change all 155's to 13's (or 13/10's) would be best. "Mapping
the Atari", Codebuster, your favorite assembler, and a good bit of stamina
would be all you would really need (assuming a working knowledge of the
Atari OS & the 6502.) I would advise against your above suggestions due
to possible problems with compatability. Your best bet would be to write
a general PUT_BYTE routine that does the conversion and have PUT_RECORD
and PUT_BLOCK call PUT_BYTE directly for each character.

2093. Atari to NEC SilentWriter LC-800

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-08 00:12:29 UTC
From: wrd@tekigm2.MEN.TEK.COM
Message-ID: <4455@tekigm2.MEN.TEK.COM>
Source record: 116047

Help! Am trying to use one of my spare Atari's to download files and print them out on a NEC SilentWriter LC-800 laser printer at work. However, none of the standard Atariwriter+ drivers seems to work -- I say seem to, as I have only tried what I thought were logical ones. There is a method of developing your own drivers, but it requires that you know the decimal codes for various items, such as line feeds, etc. I cannot find any of this information in the user book that came with the printer. Am trying to use it in the parallel mode, of course. Can anyone help that may be using a similar setup.

(While, it probably is moot, the exact setup is a 800XLE (256k upgrade in 130XE mode, 1050 disk drive, Axiom AT-846 parallel printer interface and centronics parallel cable to parallel port of the NEC.)

Thanks in advance,

--Bill--

I'm fairly sure the 850 interface just converts all $9b's to $0d$0a. You just
can't have $9b's in your graphics (try 7-line graphics).

Stephen,

I am at the University Of Idaho and have been thinking about writing a C compiler of my own for the Atari 8-bit computers. But I have had no success in finding the LEX and YACC specs for C, or for that matter any useful specs at all. I have recently obtained a copy of CC8/ACEC and have not yet got a chance to look at it too closely. Im on a VAX right now but am not sure that it is an 11 or not. Unfortunatly it does not run UNIX but it has EUNICE. I have access to a HP-9000 running HP-UX but I would be interested in trying to work with it. No guarentees though, I'm not sure I could ever get it ported (This VAX is quite old, as is the software). Does your code support standard C floating point operations? I know that none of the other available C compilers support it. Please send me some preliminary info and I will see if it is at all possible.

Paul Amonson
AMONSON@IDCSVAX (BITNET)

P.S. I tried sending E-mail but got it back as "Address Unknown".

In article <746@sunkisd.CS.Concordia.CA> you write:
>The first program will have to do serial-parallel conversion quickly enough
>to operate at 1200 bps. Timing will be critical too, so I plan on using
>interrupts triggered by POKEY's hardware timers. If you have any comments
>of the type 'it is impossible' then let me know. I figure it's possible
>because I think Supra/MPP has a 1200 bps modem that connects to the
>joystick ports, and one of the Volksmodems does that too.

I dont think this is possible, as 1200 baud modems thru joystick ports
rarely work. I had a joystick port modem and the max I could get out of
it was about 750bps. If you wanted to built such a thing, it would have
to use the standard I/O connecter as the 850 does to keep up with a 1200
baud and definetly with a 2400 baud modem. I would be interested in knowing
what you find out however, as I would like to get some recent software for
my 8bit, as I dragged it outta the closet a few months ago and realized the
newest stuff I had was over 5 years old.

Eh? How so? The only true 80-column terminal emulator I have, which I'm
running right now, is written in ACTION!. Granted, a cartridge is less
convenient for some folks, and my DOS won't run the compiled executable
(I have to recompile each time to use it)...

By the way, has anyone gotten either Deep Blue C or InterLisp/65, available
from Antic Software?

Folks, I'm the author of the CC8 compiler.
[...]
Send e-mail if you're interested.

I did, but it seems to have fallen into a black hole, thus this
broadcast to the net.

I'm VERY interested in getting hold of the source; Please, by all means,
send a copy. It doesn't matter what shape it's in, I have access to
more than enough to vaxen and things to compile it and get some good use
out of it.

2102. Re: 850 Interface Handler Code - attn Jean Goulet

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-10 00:18:31 UTC
From: Chris_F_Chiesa@cup.portal.com
Message-ID: <16951@cup.portal.com>
Source record: 115906

In another article whose header Portal doesn't pull into the reply, Jean Goulet writes:

> Luckily if you use FTP and OPEN 36.8.0.46, and go to the 8-bit directory,
Ah, it must be nice to be able to do FTP... never had that luxury ... :-)

> This leads me to ask, if you open up the R-verter, what hardware do you see?
> My guess is that it's got chips for converting RS-232 signals to TTL signals

I believe there'd have to be more to it than that; more below, in the section on pin-to-pin SIO/RS232C correspondence.

> Now I have a few questions regarding the 850:
> - which serial port on the 850 do you connect a modem to? (1-4)

Almost ALWAYS port 1. On the real, true, 850 (and most other terminal-driver boards in existence, for this and other computers, apparently!), the different ports are electrically a little different, e.g. not all "control" signals (DTR, CTS, RTS, etc.) are available/present on all ports. Port 1 is the ONLY one on which ALL signals are present, as I recall.

> - which pins are used on the atari SIO cable, and which RS232 signal does
> each pin correspond to? The table below is waiting for the answer.

Alas, there IS NO direct pin-to-pin correspondence; the information is passed in totally different ways, over the CIO connection, than over the RS232 serial port(s). For what it's worth, the SIO pinout looks like this:

Each digit represents the "pin number" of the pin at that position:

2 4 6 8 10 12

1 3 5 7 9 11 13

1 - clock input 8 - motor control
2 - clock output 9 - proceed
3 - data input 10 - +5 / Ready
4 - Ground 11 - Audio Input
5 - Data Output 12 - +12 V
6 - Ground 13 - Interrupt
7 - Command

Notes:

1) Pins 7, 9, and 13 are "active low."

2) This obviously has little of anything to do with RS232; the cir-cuitry in the 850 interface builds those signals for the ports, the CPU has nothing to do with them.

3) I call your attention to the presence of 12V on pin 12 -- surprise!

> (I added a column for the R-verter in case it's different)

Alas, I have no information for you about the Rverter...

> That is, the modem will connect to my RS-232-to-TTL
> converter, and that will be connected to the 400's joystick port, and the
> 400's SIO port will be connected to the XE's SIO port.

You're going to have to do more than just convert signal levels, from the look of it.

(Accidentally deleted the part about needing to know the difference between "sending data" and "sending commands" to the 850... That, I believe, is referred to in the official literature as "data frames" and "command frames" sent over the SIO bus.)

This stuff comes from Section 9 of the Atari OS User's Manual... This is the section describing the SIO Serialk I/O Handler...

"... All bus transactions are expected to conform to a universal protocol. The protocol includes three forms, stated below (as seen from the computer):

Send command frame.

Send command frame and send data frame.

Send command frame and receive data frame.

The values of the W and R bits in the status byte select the command form."

(The "status byte" referred to, is that at DSTATS (hex 0303) when an SIO call is made. The W bit is bit 7 (high end), and the R bit is bit 6.

W,R = 0,0 means "no data transfer associated with operation"
0,1 means "data frame is expected from the device"
1,0 means "data frame is to be sent to the device"
1,1 is invalid)

There's a whole flock of information on the electrical characteristics, byte and frame organization of data etc. over the SIO bus... Too much to type in here-and-now; Jean, send me some E-mail and remind me "section 9, OS Manual, page 145"!

2103. PC-to-Atari progress, or lack thereof

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-10 00:37:12 UTC
From: Chris_F_Chiesa@cup.portal.com
Message-ID: <16952@cup.portal.com>
Source record: 115907

I picked up the program, posted here a few weeks ago, for the IBM-PC to write disks in "double-density MYDOS format," and after transferring it to three different computers in two states (NOT counting Portal in a THIRD state) I finally got to try it last night on a real, true, honest-to-IBM PC-AT!

Unfortunately, it didn't work very well: designating the program as "TOATARI," typing the program-name alone sufficed to invoke it and produce a help screen, where I found that the command

TOATARI /I A:

should format, or /I)nitialize, the disk in drive A:

The command
TOATARI /L A:

should list the directory of the disk in drive A:, and

TOATARI /W filename[,...] A:

should write files to the disk... all of this being in MYDOS format, supposedly

I started with the "initialize" command above, and got an error immediately: "Error formatting track 0." I tried the SAME command a SECOND time, and got NO errors.

Next I tried to write some files onto this newly-initialized disk, and got another error: "unable to read directory for update" on the disk!

In order to further investigate THAT, I tried the "list directory" command format, and got the same sort of error: "Directory unreadable" or whatever the wording was; you get the gist of it.

I thought, perhaps the pre-existing IBM tracks etc. on the disk I had used, were interfering with operations, so I took the disk and ran it through a magnetic bulk-eraser, returning it to its off-the-shelf state. No dice; SAME sequence of errors, including the on-again, off-again formatting error.

I tried the whole thing over again with a completely different disk, and got all the same errors. NOTHING worked.

Now, the 64-dollar question: can anyone suggest what may be going wrong?? Am I doing something wrong, am I using the wrong computer, or has the whole thing been a big put-on from the beginning? Has anyone else gotten this to work?

I was "iffy" on trying this in the first place, but now that I WANT to use it, it doesn't work. Maybe it's just theUniverse's idea of poetic justice!

Thanks in advance for all help!

>By the way, has anyone gotten either Deep Blue C or InterLisp/65, available
>from Antic Software?

I've used Deep Blue C considerably, since I have nothing better. I bought my
copy back when APX still existed. I just recently bought Deep Blue Secrets from Antic.

- It is a rewrite of Ron Cain's Small C. This means:
- no structures or unions
- no arrays of dimension greater than 1
- no floating point numbers
- functions can't return anything but 16-bit integer
- no sizeof operator (useless without structures anyway)
- no typecasting (not enough data types to need it anyway)
- nothing fancy like register or static variables
- other stuff missing too.
- It produces fairly slow code. This is understandable, if you know how
its runtime engine works.
- It compiles at an ungodly slow speed.

To be fair, here are some advantages (as compared to C/65, at least)+
- It doesn't need line numbers. OSS loves line-numbers. They're needed for
Mac/65, and C/65. What a waste.
- It takes lower-case input. C/65 doesn't. What a pitiful waste.
- I haven't run into any major-ugly bugs.
- Source code is(possibly was) available, in Deep Blue Secrets, from Antic.

- It comes with fairly complete libraries, including routines for graphics,
sound, and player-missile graphics.

In general, I've been satisfied with it, given the limitations of the 6502.
I've used it to write a number of utilities for SpartaDOS. I tried to do a text
editor, but it was just too slow
for that.

Given the choice between Deep Blue and C/65, I'd choose DBC. I can't compare
to Action! since I've never used it. I get the impression that I should.

Ron Harding.

Gil --

This is ridiculous! Every time you write me I write back, and every time it bounces. The only way to get through to you seems to be to post here. No bounces, who knows why!

The following is the complete text of what I've been trying to send you for the past five or six weeks, so I hope it goes through.

For those of you interested, this document contains the details of constructing a null-modem cable and transferring files from an Atari to some other computer, without using modems. You may THINK you'll "never need that," but - trust me; you WILL someday wish you'd saved this! :-)

Subject: Re: Transferring files, ATASCII <--> ASCII, et al
Lines: 206
Date: Sun, 12-Mar-89 12:05:50 PST

Hi Gil!

Sorry for the delay in this reply; I've been busy hosting friends from out-of-state for a week or so!

I'll get to the file-transfer stuff in a sec; first though, a few words about Portal.

Judging from the wording of your inquiry about AI openings, it seems you are thinking of Portal in the same light as most of the other nodes on this Net -- a company (or perhaps a school) doing business, with all the users being employees, students, etc. All in all this is quite a natural assumption -- I, in my student days, never thought otherwise myself.

However, our common conception turns out to be a MISconception! Portal is actually a "subscriber" service -- a "pay as you go" system, if you will. It seems to be run by a relatively SMALL group of people; I'd say nearly ALL the 'username@Portal' postings you see, are from SUBSCRIBERS such as myself!pag

Therefore, I myself have nothing whatsoever to do with Portal per se -- it is merely my access point to the Net, at the present time. I don't even LIKE it all that much, for various reasons not apparent on your end... But I digress. I will attempt to forward your compliments about Portal users to the appropriate system managers, so that they will know that you have been kindly treated by Portallers in general.

Now, about file transfers! I'll have to pop out of my terminal program for a moment, to find the files I originally tried to send to you and Mr.

Bartlett, way back when... hang on!

Okay... here's the FIRST posting I tried to send; I can't find the second -- maybe I lost it... but I should be able to re-create it and make the same points again, after this first "article."

Gentlemen -

In regard to your file-transfer yearnings, allow me to recommend a simple item known as a "null modem" cable. This is a cable which, when connected at one end to computer A's serial port, and at the other to computer B's serial port, makes EACH computer "see" the other as a "modem connection." You could, if so inclined, run a BBS (Bulletin Board System) on computer A, and "log into" it from computer B. Or, you can run a terminal emulator on each, and "talk" back and forth... and if those terminal emulators both happen to support the same "file-transfer protocol," VOILA -- you can transfer files!

The construction of such a cable involves running at least THREE conductors (wires) between the computers: "SEND data," "RECEIVE data," and "Signal GROUND." These are typically assigned to pins 2,3, and 7 of a standardized "DB-25" (the type of jack) or "RS-232" (the 'standard' that defines the signals) plug or jack. Obviously, you will need the appropriate "plug" or "jack" to "mate with" your computer's existing serial port, whatever that may be; if you are not using the "standard" 25-pin connector (you may well not be; in fact, your computer may even require an extra circuit board to do serial I/O), consult your manuals to find the "pinout diagram" of the serial port, and connect up a cable as follows:

Computer 'A' end of cable Computer 'B' end of cable

"Transmit Data" (or "TD," ----\ "Receive Data" (or "RD,"
or "SEND data") ----/ etc...)

"Receive Data" ----\ "Send Data"
----/

"Signal Ground" (or "GND," ----\ "Signal Ground"
or "Data Ground") ----/

(If you ARE using "standard RS232 25-pin" or DB-25 plugs/jacks, this may be expressed in terms of "pin numbers" (these are molded, very small, next to each jack-pin or socket-hole) as:

pin 2 ---> pin 3

pin 3 ---> pin 2

pin 7 ---> pin 7

)

It is possible that your particular computer may require additional conductors (wires) or signals; what I have shown is extremely MINIMAL and may need to be extended. If you get as far as what I've shown, and you plug it into both computers, and they still won't "talk" to each other, contact me again.

I would like to suggest that you DON'T write to me at the address that appears with this message! That is the address of my "school" account, which remains in existance even though I graduated some time ago, and which I rarely if ever log onto. I have subscribed to (cough cough) "Portal," however, and can be reached there by sending E-mail to

Chris_F_Chiesa@cup.portal.com

If that mail bounces, THEN try sending here -- but the turnaround will be a lot longer!

Anyway, that covers making the cable. As for terminal programs, try to find a program for EACH computer that supports "file transfer." This is DIFFERENT from "ASCII capture," so be sure you've got some sort of "protocol" besides just ASCII. (That keeps your files from being garbled if there's "interference" on the line; admittedly, much more of a nuisance while using a modem than with a direct cable, but essential if you want to transfer anything other than plain text. I regularly transfer executable "binary" files, for instance.)

Some popular protocols that you should be able to find are "XMODEM" and "Kermit" -- I know for a fact that BOTH exist for the Macintosh and the Atari, and that Kermit exists for the PC, so you should be able to get going with this arrangement in very short time.

It occurs to me that I may have "talked over your head(s)" in some areas, or glossed over others. Please let me know how you make out with this, whether you can or cannot get it to work. I didn't notice where either of you are located physically, but for what it's worth I'll tell you that I am in Rochester, NY, and can be reached by telephone at (716) 342-5914. (If that's busy, you can TRY (716) 544-5188. These are both HOME numbers; I usually work 8-5 PM, Eastern.

Good luck to you both!

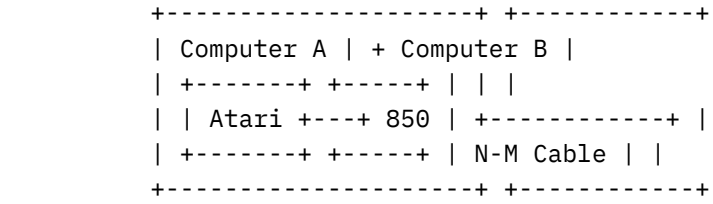
Chris Chiesa

Okay, that's the FIRST thing I wrote to you. The second, sent a day or two later, came after some thoughts on the subject. The gist of it was as follows...

It suddenly occurred to me that if you are using an Atari 8-bit computer, some of the previous message may be misleading. Specifically, the references to "your computer's serial port" may be misleading. On the Atari, the only built-in "serial port" is the 13-pin "SIO" port. This is *NOT* the "serial port" of which I spoke in the null-modem-cable discussion (above)! Atari did their serial I/O differently than most computers, probably because they were "there" fairly EARLY in the field.

In order to apply the "null-modem cable" idea to an Atari 8-bit computer, you'll need an additional piece of hardware of some kind, to transform the Atari SIO-port signals and lines (wires) to those compatible with other computers. This is the function performed by the Atari 850 Interface, or the "P: R: Connection," or similar devices you may have heard of.

It might help if you think of your Atari-plus-external-conversion-hardware as ONE unit; it doesn't matter WHAT the "external conversion hardware" is, as long as its OUTPUT is compatible with the RS232 standard as briefly covered in the first message. In "computer A, computer B" terms as used in that message, it would look like this:



What this shows you, basically, is that "Computer A" from the first posting, consists of the Atari PLUS an 850 Interface or equivalent signal-conversion hardware. Feel free to ask any questions you may have, of course.

A second consideration of file-transfer between Atari 8-bit and other brands of computers, arises from a point of Atari internal design. Namely, Atari took the liberty of redefining some of the standard ASCII character codes, to the point where every OTHER computer's end-of-line character, the "Carriage Return" (ASCII 13), is of no special significance, and the "ATASCII" (Atari ASCII) character 155 is used as the end-of-line marker. This means that if you want to transfer text between Atari and other computers, you need to allow for, and perform, the conversion from standard ASCII, to "ATASCII". This can be either very tricky, or very trivial, depending on how you proceed.

Fortunately, most terminal (and file-transfer) programs for the Atari 8-bit computer, have long been aware of this need, and have facilities build right in to perform the conversion DURING file-transfer. A "switch" for "ASCII/ ATASCII" usually appears somewhere, either on a menu or as a command or option at a prompt. If you use this switch correctly, you need never do any other conversion; on the other hand, if you DON'T use it, use it WRONG, or use a program that (heaven forbid) DOESN'T HAVE it, you may find yourself trying to word-process what looks like a lot of gibberish. In a sense, this is just an "extension" of the need, in some file-transfer protocols, to "tell" the program in advance whether you will be transferring "text" or "binary" files. In fact, in Kermit65 on the Atari 8-bit, in addition to the usual "set file-type binary" and "set file-type ascii" setup commands, there is also a "set file-type atascii" command to do this very thing!

(And, for the record, in "850 Express!" which implements XMODEM file-transfer, there's an option on the menu screens for "ASCII" vs. "ATASCII" mode. Unfortunately, it affects terminal mode as well as transfer mode, with the result that you may need to toggle back and forth a lot, but if you "play" with it you should be able to find a combination that works.

Okay, Gil, that's the gist of what I said last time; I hope this reaches you! Please feel free to contact me by whatever means are convenient, if you have questions. I used to have a job, at school, helping people all over campus, and I miss it, so here I am all revved up with no place to go!

Good luck!

Chris Chiesa

>that entrance for you!

Amazing! Just last night I spent about an hour bumping my head
(well, my character's head) on every square of every wall
that surrounds that area. I was convinced that there must be
a secret door here somewhere.
Now, are you sure that we are not supposed to find an
entrance to that area by finding/doing something first
somewhere else in the game? And how in the world did you find
out about those extra rooms (and how to make a passage to them)?

I also have 2 questions to any AR players out there on the net:

1) I got a clue from a song at The Club that went something like
this: "The treasures below will provide many answers.....the
Floating Gate may hold the key...." Now, I assume that "The
trasures below" means The Dungeon. I have not played it yet, but
a friend tells me that you can obtain a strange key there. But
I thought that you can't bring your character from The Dungeon
back into The City! So, how do you get that key to the Floating
Gate (or do you)?

2) Are there any instalments of AR, besides The City and
The Dungeon, out there for the 8-bit Atari? How about any other
computer? Do they plan to compleat the series?

I would appreciate any answers to these questions.

Sorry for using the net as a mailing sys. But as we say here mail
is sCWRUed up :-)

I want to thank all the netters for the help on null modems and stuff to
get atari to pc ... especially Chris Chiesa. Now to see if it works...
I'll keep you guys posted.

Chris: Thanks for your persistance. I now have such a job on campus
and I have a great time at it. Ps. I may be in Rochester this summer
if things materialize (knock on wood).

Gil Yehuda

BTW: I got an interesting question, maybe it will stimulate a discussion:
Does the name ATARI have any relationship to atari in go --
the chinese board game. In go if your stone is surrounded by three
sides then it only has one freedom to extend into. If it doesn't grow
forward then it can be captured. Hmmmm.

From: ajy2208%ritcv@cs.rit.edu
Message-ID: <1048@cs.rit.edu>
Source record: 115915

I have The Dungeon for my 8-bit, and believe there is __NO__ way to take anything you have discovered in the Dungeon back to the city. The Dungeon does provide means to CONVERT a City Character to Dungeon Status, but I remember the manual explicitly stating that once you go into the Dungeon, there is NO way back.

I like the Dungeon a LOT, although I wish I had more time to play it. It is a fantastic game, and I wish there were more like it for the 8-bit. There is so much to discover in the AR series, it's incredible!!!!

By the way, in the Dungeon, the Oracle is located directly under the Floating Gate. In order for you to give him advice, you need to give him special object(s). I've gone to him before, but I don't recall off the top of my head what I've 'thrown' to him (actually he's a big, fiery eye).

Anyone care to discuss what they've found in their travels through the City and Dungeon?

From: rcbamw@eutrc3.UUCP
Message-ID: <531@eutrc3.UUCP>
Source record: 115916

In a recent article I read something about problems with a program, written to read and write Atari disks on a PC. Since I once considered writing a program like that myself (but gave up when I discovered that it was pretty hard to make the floppy controller write an extra long sector the 1050 needs for timing purposes, since it doesn't use the index hole...), I was very interested.

The article said that the program concerned had been on comp.sys.atari.8bit. Would the author please be so kind to send the source to me or to get in touch with me to exchange ideas?

Many thanks in advance,

M.J. Waucomont

> WANTED: PaperClip Word Processor.
> Looking for the 'newer' version that supports the extra memory in
> a 130XE and has a spell checker. I have searched everywhere and Batteries
> Included doesnt sell it anymore.

Batteries Included folded over 2 years ago. They were killed by a mixture of low sales in the ST world and some management mistakes. Electronic Arts bought the rights to Atari PaperClip and all the other BI products from the receiver who was holding the assets. EA stopped shipping new copies of Atari PaperClip about the middle of last year.

You want version 2.0 or 2.1 of PaperClip. 2.0 was released thru BI and included the 130XE support and the spell checker. Version 2.1 removed the copy protection (no more hardware key) and also fixed a bug in spelling words starting with "z". (The 2.0 program file was missing 16 bytes at the end. Those bytes contained the index into the "z" words on the dictionary disk.)

You might be able to get a copy of version 2.1 from EA if they still have any in stock. (I haven't had any reports from them since last year so I doubt they still have any stock.) There are some distributors who still have copies, your local dealer (assuming you have one) might be able to find a copy by calling them. Some of the mail order houses also had copies. Be careful with the distributors and mail order places, they may still have old versions with out the spell checker or the 130XE RAM support. (Version 1.2 and 1.2X added support for the extra memory in the 130XE; version 1.1 only used the memory under the OS ROMs in XLs/XEs; version 1.1A is a downgraded version 1.2 (some features removed) which was shipped on a flippy disk, C64 version on one side Atari on the other; I wouldn't recomend version 1.0 to anyone, it was only shipped for about 2 weeks before 1.1 was released.)

> If I cant find this, do any of you have any recommendations on word
> processors? Nobody at the stores in my area have any experience with
> 8bit software. It must have a GOOD spelling checker and preferably use
> the extra memory in the XEs. Recommendations, anyone?

The only other word processor for the 8 bits that I know uses the extra RAM in the XEs is AtariWriter+. Unlike PaperClip it doesn't manage the extra memory without help from the user. The user can tell AW+ which bank to load text into, and when a bank gets full the user must choose another one. PC just told the user there was a lot of RAM, it made all the decisions about where to place text in memory. The user didn't have to do anything special. Personally I think PaperClip is

much better than AtariWriter or AtariWriter+, but then I have a very obvious bias in the matter.

Both PC and AW+ use the versions of the same spell checker.
ANTIC also used to sell (and still may) a stand alone version of it also. The only difference between the three versions are the dictionary files, some words were added/removed between each version. (NOTE: the dictionary disks can NOT be exchanged between versions.)

There are a couple of newer word processors out for the 8 bits.
I haven't used any of them so I can't say how good/bad they are. They are cheaper than PC and AW+ used to be. (Prices on both PC and AW+ have dropped a lot.)

From: "Information Week" - Issue 215 (4/10/89) Pg. 36

Atari Computer began shipping Portfolio, a 1-pound MS-DOS
machine. Retailing for $400, it's expandable to 640K, runs
on AA batteries, and offers an 8-line, 40 char. LCD display.
The handheld unit comes with a text processor, Lotus 1-2-3
compatable speadsheet, and built-in modem.

This is the first I've heard of this. Thought the rest of you Atarians
would like the news as well.

Signed,
Marcus "Orphan Computer" Prickett (I keep my 800XL next to my TI99/4A :-})

Yes, that's true. I have come across a nice little gem on a BBS that
allows you to edit a Dungeon character...to raise his stats, gold,
location, etc. But still you're trapped in the Dungeon. Anyone care
to take a crack at writing program to convert a Dungeon character
back to a City character (without all your "discoveries" of course,
which the City wouldn't recognize anyway)?

> I like the Dungeon a LOT, although I wish I had more time to play it. It

You and me both. AR is without a doubt the best game ever made for the
Atari 8-bits. Unfortunately, Datasoft was bought out and they have
just recently scrapped the Alternate Reality project...for the Atari
as well as other machines. I wish they'd reconsider, or that another
company would buy the rights to the name...

Message-ID: <6789@bsu-cs.bsu.edu>
Source record: 115925

Mike Barthelmy wrote asking for VT100 emulation software; this question sure comes up a lot!

Mike, you would probably find Kermit65 (John Dunning's port from the C64) satisfactory. It emulates the VT100 in both screen and keypad, and has a lot of other nifty features besides: several selectable different display modes, Kermit file transfer...

Kermit65 comes either "with the standard Atari R: handler (for the 850) prepended," or "WITHOUT the... handler..." If you get the LATTER, you can also obtain and pre-load (or prepend to Kermit65 itself) a handler that will let you plug an SIO cable directly into the SX212 and use it THAT way. This method allows full Kermit capability just as though you were using a standard modem on the 850 Interface..

If you want more details, post to the Net; I probably ought not be posting from this username, as I am no longer a student. I can be reached on the Net with less paranoia on my part, at

This is strange.... the 'Chemilion' DIDN'T work with the P:R:? I had a
home-brew Rverter and that program worked for me. In fact, I got 850 express
to work and just about ANY 850 program with the one exception of the
vt100sq program.

Have you tried KERMIT?
If you haven't, I would recommend it highly. If you have ftp access (in any
way... ie: friends...), KERMIT is available over the net...

Quick question. I could have sworn that I heard a rumour a while back that Nolan Bushnell had signed a contract to develop a bunch of new games for the 2600,7800 and XEGS. On the front page of last weeks MacWeek there's a story about Bushnell. Seems he just became chairman of Preferred Publishers - a Mac development company. (as an aside, he also hired former Atari 8-bit software guru, and more recently Apple employee, Russ Wetmore) So is Nolan going to be doing both, or did the Atari deal fall through?

-Ray

2127. 80-track floppy drives on Atari?

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-16 01:13:07 UTC
From: charles@c3pe.UUCP
Message-ID: <6729@c3pe.UUCP>
Source record: 115931

Has anyone succeeded in attaching an 80-track, double-sided, 5-1/4" floppy drive to their Atari 8-bit computer? Doesn't the ICD box which sits on the parallel bus do this for the XLs?

Is there any way to use, say, a 1050 with one of the popular plug-in enhancements to accomplish this feat?? I'm well aware this would probably involve downloading code to the enhancement itself.

Thanks for any replies; I'll be glad to summarize to the net.

The XEP can act as a printer buffer as well as an 80 col out, but will not
do both at the same time. It does graphics 8 (320x200?) bitmapped graphics
and outputs composite video. It should do a decent vt100 emul with the
right software (but it wouldn't go 9.6kbaud :-).

Are you implying that the 'right software' does not exist yet?

Does anyone know if a good terminal emulator for the XEP-80 exists?

2133. Atari 800 Complete System for Sale

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-17 18:19:19 UTC
From: pipprg@jhunix
Message-ID: <1464@jhunix.HCF.JHU.EDU>
Source record: 115937

Greetings Atari Junkies !

I have some pretty 'vintage' equipment (all in top condition) for sale:

Atari 800 48K (wow) home computer w/GTIA graphic chip
850 interface unit for printer/modem/etc
830 acoustic coupler modem (300 baud)
Touch Tablet drawing device
BASIC, Starraiders, Artist, Telelink, PACMAN carts
Joysticks
Indus GT 5.25" disk drive
Commodore 1702 Composite Color Monitor
Tons of disk software - great games, etc
Books, cables, wood computer desk.

all for $ 600.00

Any takers ? (I'll pay the shipping !)

2135. Help!

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-17 21:33:44 UTC
From: slackey@bbn.com
Message-ID: <38777@bbn.COM>
Source record: 115939

Well, I tried a few new&different things over the weekend, and ran into
a few good problems.

1. I am trying to use SIO directly. I am doing this so I can do physical
sector accessing of the disk. (I really want to do this, so don't try
to talk me out of it.) I was successful in reading 1050 and 810 density
disks, on both the 1050 and XF551. I haven't tried writing yet.

My problem is: I get error# 138,139,144 which are device errors, NAK's
and timeouts accessing DSDD disks on the XF551. I assumed that you
just set the byte count from 128 to 256. Some of the data I read
might have been right, but with all the trash it was hard to tell. I
tried setting the byte count back to 128, but the symptoms were the
same. I turned the drive off and back on again, and got the same.
Apparently, there is something different you must do when accessing DD
disks.

2. I couldn't get AMAC (the Atari assembler) to work under DOSXE. It may be
because you need the DOS 2 handler in memory to read the assembler in, but
it takes up too much space. Is there any way to get around this, or
possibly get a DOSXE version of the assembler? I believe AMAC is copy-
protected. Once I tried copying it to another disk (so I could rename it
to AUTORUN.SYS, not to pirate it!) and the copied version did not work.
I had made my assembly source under DOSXE, and could not assemble it.
So, I was about to copy it to a DOS 2 disk when I remembered that DOS 2
support under DOSXE is read-only! Now what?! Then I remembered... C:!
I got my shovel and dug out the ol' program recorder, copied to C:, and
it worked! Of course, now under DOS 2 I do C C:,D1:FOO.ASM and get the
response ILLEGAL OPERATION or something. Oh well... 10 DIM A$(128),
20 OPEN #2,4,0,"C:", 30 OPEN #3,8,0,"D:FOO.ASM", etc. At last this worked!

Well that's it. I am SECTORing for two reasons: one to be able to transfer
files between Atari and PC's, and the other for a program I am writing.
If you know the answer (or even just guesses-I'll try anything!) to #1,
PLEASE answer. #2 I can get around, although I would like to do all my
development under DOSXE.
Thanks! -Stan

2136. Finding the HSYNC signal

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-17 22:11:36 UTC
From: jean@maxwell.Concordia.CA
Message-ID: <773@sunkisd.CS.Concordia.CA>
Source record: 115940

Hello. I've been looking into making a light pen for my computer, and I think the design is complete, except for one important detail. My circuit needs to be restarted every time the electron beam starts a new horizontal line, so I figure the HSYNC signal is what I need. Unfortunately I don't have the schematics for my computer, so I'm wondering if someone knows if this signal is availble on the 130XE motherboard. I looked at the schematic for the 400/800, but it looks like color, brightness, and timing info are mixed together inside one of the chips and sent out as the video signal.

Would it be easier to extract HSYNC from the RF plug (or the composite output? Or the luminance output?). If so, what kind of circuit would I need (comparator, etc.)?

By the way, I realize the computer has hardware for decoding the position of the light pen, but my experiments have shown that the x-input is so inaccurate that it's unusable. My circuit will have a resolution of 640 on the x-axis (overdesign is better than underdesign). I'll use the y-coordinate output from the computer, though.

From: ajy2208%ritcv@cs.rit.edu
Message-ID: <1059@cs.rit.edu>
Source record: 115942

ICD's Multi-IO board that attaches to the parallel bus on the XL and XE computers does NOT allow floppy drives to be connected. Just Modems, Hard Drives, and Printers.. :) However, the ATR8000 allows just about any type of floppy drive to be connected (even 3.5" drives I imagine). While most (all?) DOSs will work with the ATR, only a few DOSs (like SpartaDOS and MYDos) will allow you to format disks in a format different than what you'd normally see. My roommate had one, and he had 2 DD/DS and 2 DD/SD IBM drives hooked up to it. The ATR8000 also has a centronics printer interface and a serial interface (for the modem). AND it has CP/M capability (ooooooooooooooo).

I may be wrong (disclaimer!) but I don't think there are any 1050 enhancements that allow you to connect external drives..
There was a drive that allowed you to connect more drives, but the name escapes me (TRAK? Percom? Rana? Naww, definitely not Rana, those drives were a piece of junk!)..

As far as I know, there are no programs for the XEP80 that support VT100 (or better) emulation. I wish there were, as it would be VERY useful to me. I do have several other term programs that work with the XEP80 though. These include AT880 (features: autodialer, xmodem, ymodem, ymodem batch, up to 9600 baud [who said the XEP80 wouldn't support 9600???], ATASCII/ASCII, and others.. it has a nice HI-RES title screen too!!), VT850 (a program that emulates a VT100 with a VT200 keyboard. works either with or without the XEP80), 850 Express! (all modem input/output goes through XEP80, and the menus appear on a 40 column monitor/tv (if you have one).

Despite the availability of these programs for the XEP80, I still prefer to use Kermit65 (which has good VT100 emulation and 80 columns without an XEP80 [it uses Graphics 8 and draws the characters--can't keep up with 2400 baud without sending ctrl-s/q now and then]), and DEterm-- a fantastic term program which continues to get better and better.

It's interesting to note that all these programs are PD or Shareware!!

Both Chameleon and Kermit65 work with the PR:Connection.

Chameleon will only display forty columns at a time. However, you can scroll right, to read the other other 40 columns, or left to return to column zero again.

Kermit65 has a vt100 terminal emulator built in.

The following applies to both Kermit65 and Chameleon.

Examine the directory of the floppy disk that came with the PR:Connection. You should find a program called, if my memory serves me correctly, PRC.SYS.

Copy PRC.SYS and the Chameleon/Kermit65 file to a newly formatted disk and then append Chameleon/Kermit65 to the PRC.SYS file.

If you are using Atari DOS 2.0S, use the copy option (C). That is, at the "copy from,to" prompt type: (Chameleon/Kermit65 filename),PRC.SYS/A.

Rename the PRC.SYS file AUTORUN.SYS.

Use option number 2 at the Chameleon menu prompt.

2142. More on SIO

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-20 21:45:14 UTC
From: slackey@bbn.com
Message-ID: <38936@bbn.COM>
Source record: 115946

OK, I just KNOW there are many many of you out there who are just dying
for an update on my PC-DOS-to-Atari disk file transfer progress...

The way I left it was I could read 810 and 1050 format disks OK, but was
unable to read XF551 (DD) disks at all. Well, part of the problem is
fixed, that is I can read Atari-formatted DD disks now. Apparently what
had happened was I had put the XF551 into some bogus state by attempting
to read the PC-written disk, and then attempting to read sectors 1,2,3
of an Atari disk (which, by the way, Atari keeps in SD. Question 1.
Is that done by software in the computer, or by the drive itself?)

As I recall, when I used Spartados DSDD XF551, it seems those sectors
may have been formatted DD because it took a couple "tries" before
a DD would boot. Question 2. Does anybody know?

Finally. I still can't read PC-DOS disks. Are they in 256-byte sectors?
Is there some other incompatibility that will stop me? How do I find
out?

Why not... Is there more up-to-date information available from Atari,
later than the tech notes? Specifically on DOSXE and/or the XF551?

Oh - I had noticed in the DOSXE book that disk files can have holes in them,
that is, NOTE/POINT don't have to add on to the end of a file. I read on
to see how this works, and found that the file format includes a sector
map, apparently to allow NOTE/POINT to work even when a file is copied.
(The NOTE/POINT implementation is incompatible with DOS2, which actually
uses physical sector numbers.) I thought this was really neat! Do other
DOS's have this feature? Just curious.
Thanks, your help is appreciated. -Stan

2143. Atari 8bit EPROM burner & MAC 65 cartridge wanted

> I know this questions been answered a ZILLION times, BUT do anyone know
> of an easy way to transfer IBM PC files to an Atari???

Here's a tack I haven't seen discussed yet, but which I started to implement some years ago before being distracted by other things:

Find an Exar XR2206 (single-chip, monolithic function generator) and an MC1489 RS232 receiver (or a well-placed diode or two :-). Wire them up to produce the same FSK mark and space frequencies as Atari uses for their cassette interface. Write an IBM PC application to produce the same headers, trailers, checksums and IRG as the C: device uses. Then string it all together with your favorite portable cassette recorder (or high-quality stereo deck).

Since the XR2206 generates a phase-coherent frequency-shift signal, you will probably get even better reliability than simply switching between two square waves as with the Atari recording scheme. You might even try persuading the cassette handler to use a baud rate higher than 600 - since I believe that FSK was used some years ago in a 1200bps half-duplex modem over phone lines (3kHz bandwidth), you may be able to get away with 4800bps! (If the 1010 can't quite keep up, you might want to also experiment with the XR2211, which for me has proven even more reliable at reading Atari tapes than the 1010.)

Gary,

I would love to get the source to Kermit65.. I have an XEP80 attached to my 8-bit system (XE,1MegMIO,2 20 MEG HD's,two monitors,2 DD drives,Sparta X,R-Time 8,and more) that I would love to get to work with Kermit65. I have tried to use it, but unfortunately it didn't use all 80 (it would go to the next line at 39 characters as you said)..

To anyone using the XEP80: Have you found any good word processors that use it? I know there is at LEAST one (MicroWord, I think), and that some year Atari MAY decide to distribute AtariWriter 80 (but I've learned not to hold my breath).. I currently use Textpro but unfortunately it doesn't work with the XEP80.. :_(

2149. Forth for c64/6502

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-21 20:57:22 UTC
From: allred@ut-emx.UUCP
Message-ID: <12298@ut-emx.UUCP>
Source record: 115953
Cross-posted to: comp.lang.forth,comp.sys.cbm,comp.sys.apple,comp.sys.atari.8bit

I have a c64 computer, and I am interested in learning Forth and/or related threaded languages. I have considered coding one from scratch using the excellent book "Threaded interpretive languages : their design and implementation" by R. G. Loeliger as a guide. The task seems a little more time consumming than I'm prepared to follow through with. Additionally I would like to start with a kernel that is pretty standard Forth -- I'm not sure I could duplicate one even looking at a standards guide. I know that a lot of companies have sold versions of Forth for the c64 computer, but I really want something that is PD, preferably with assembly source included -- I want to be able to analyze and change the code as part of the learning experience.

Please send me e-mail if you know how I could obtain such a code. If there isn't a c64 specific code, I would also be glad to know if there is an apple II, atari, or other 6502 version available. I think I could probably adapt it to work on a c64 if I had assembly source.

Thanks,

It just so happens that CSS is local (Rochester New York), and I know
the folks over there. The Black Box is being designed by Robert Puff,
author of the Disk Communicator, SuperArc,SuperDeArc, and a host of
other software and hardware products. I even got a quick peek at the
blueprints for it last time I was over at Bob's house.

I can say without hesitation that this product will be FANTASTIC! Bob
is a wizard at 8-bit products (you should see his system). I'll get
some more info about the box from Bob.

IF this little machine turns out to be what I need, it will be
a gem! YOU have any idea what this Portfolio means to me?
I'm speech impaired due to cerebral palsy. I am mobile, so a
clumsy heavy Laptop and / or DECtalker, wouldn't do me much good.
Have struggled ok with a tiny tandy for four years, but it really
is much too tiny to type on, and only holds 2 or 3 k... 3 lines
3 -short- lines of text........

And if my eyes didn't decieve me , I saw a speaker on the side...
If it can do speech synthesis, it will be a double blessing...
I will at long last- have a voice- and be able to carry on more
'normal' in-person conversations........maybe even give poetry readings.
'So, say a prayer....

My dad asked the following questions;
does it have a serial port? Does it have a paralell port?

Does it have internal disk drives...<-- answered in article, i know ;>
Is there room to add ibm compatible 1/2 cards?
Anybody selling it at discount for handicapped?

WOW!, the possibilities are astounding....... I've only waited
33 years for something like this...... Knew the tech was here, but
didn't think anybody was gonna put it all into one tidy
package so soon! YAY!......... Hey, I can dream, can't I?

Hi all! I've been interested in obtaining a copy of Kermit65 for some time now. I tried getting it off the net twice when it was posted in the past, but never had any luck getting to work. Would some kind soul out there be willing to US Mail me a working copy on disk, with the appropriate handler(s) for use with an SX212 and PR Connection setup? I will of course reimburse you for the postage and cost of th disk; or swap you for some piece of PD software that I have if you like.

2155. The Anaheim World of Atari Show -- A report

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-23 02:50:20 UTC
From: rjung@nunki.usc.edu
Message-ID: <3571@nunki.usc.edu>
Source record: 115809
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

I have just come back from attending the first(?) World of Atari show, at the Disneyland hotel in Anaheim. Since there's probably some interest from all Atarians at what took place, I'll spill my guts (somebody clean that mess up).

The show runs April 22, 10:00am - 6:00pm, and April 23, 10:00am - 5:00pm. I arrived through the doors at about 10:30am, paid $5 for a ticket, and walked in. This was a "buyer's show", which meant that every other booth was trying to get you to buy something. The crowds were already 5-men deep at 10:00 in the morning, though it tapered off to a more manageable level later in the day.

WHAT'S NEW?
I would estimate that over 40 different firms and groups were at the show, each showing a combination of new and old products. To keep this thing from going too long, I'll just touch on the highlights:

ATARI CORP. was showing off the Moniterm 19" monitor, the Calamus DTP program, the new Megafile 44 hard drive, and their up-and-coming WordFlair word processing program. Everything was running fine, and Atari expects to have the last two products available around June or July of this year. (For information about the STacy, the PC Portfolio, the TT and the ATW, see below)

GADGETS BY SMALL was demonstrating the Spectre GCR. The cartridge has a cable to let you hook up an internal- or external ST disk drive so that it will read Mac disks directly. It is expected to be available in August (FCC approval pending), with a retail price of $300. Owners of the Spectre can trade it in for $100 credit towards the GCR.

AVANT-GARDE was showing PC-Ditto II, running Microsoft's Flight Simulator on the Atari ST. I am not familliar with how fast an IBM PC runs FS in its native enviroment, but this demo was not slow in any noticeable way. According to their literature, PCD2 has a Norton SI rating of 3.0. The price is $300.

SUPRA was showing off their line of hard drive equipments for the Atari computers. Nothing new to report, though.

The DIAMOND GOS was being demonstrated (no sign of GOE anywhere). It looks a LOT more like the GEM system now, and appears to be available for sale. It comes with (I think) a paint application and a word pocessor. It comes on a piggy-back cartridge, and is transparent as DOS to the system. Rumors fly that Atari wants to market the Diamond with future 8-bits.

ARTISAN software was demonstrating two ST programs: Word Quest, which makes word search puzzles, runs in color and monochrome; and Graph Maker, which (natch) makes graphs.

HAPPY COMPUTERS was selling the Discovery cartridge (for the ST) and Happy upgrades (for the 8-bits). They also announced a new product called Quick*verter, which allows for easy conversion between Spectre, Magic Sac, GEM, and Macintosh format disks.

GRIBNIF SOFTWARE (what does "Gribnif" mean?) was showing and selling NeoDesk version 2.0. It allows custom file icons, keyboard reboot, fast windowing routes, and lots of other features. All this for $50.

SEYMOR/RADIX presented a new piece of hardware called DVT VCR. It allows you to back up your hard drive on VCR tape (up to 360 megabytes). The box connects your system to the VCR by the cartridge port. Price is $250.

IMAGEN was selling Ultrascript for the Atari SLM804/Dot matrix/HP Inkjet printers. Apparently Atari Corp. will control distribution of the "SLM 804-only" version, while Imagen gets to hawk the Dot matrix/HP Inkjet version by themselves. Rumors were that Ultrascript will also work with the HP Laserjet with no problem. Price is around $200.

CODEHEAD SOFWARE was showing Hotwire and MIDIMax. Hotwire is a utility of benefit for hard drive users; A given file/pathname can be assigned to any user-defined keystroke, and executed from the Desktop with one press. MIDIMax allows the creation of MIDI "macros" for storage or playback, which can be triggered by any MIDI event. Both products are priced under $50.

SIERRA ON-LINE was showing a videotape featuring the latest of their adventure programs: Gold Rush, Space Quest III, King's Quest IV, Police Quest II, Leisure Suit Larry II, and Manhunter: New York. The games that aren't already available for the ST will be converted "very soon".

A new(?) company, ARTISTECH DEVELOPMENT, was showing off Da Vinci, an art/animation/drafting tool. Written completely in assembly, this program ofers a lot of "features for artists by artists" (work on 12 pictures at once on a 520 ST!) at high speed. This is expected to be released in July for about $100.

MIGRAPH had Touch-Up for sale, and announced a forthcoming hand-held scanner. The Migraph Scanner package will scan any type of printed material, and turn it into .IMG, .PC*, .TIF, MacPaint, Printmaster, and more. It will come bundled with scanning software and an image-editing accessory. No price or release date announced.

BECKMEYER DEVELOPMENT TOOLS talked about Micro C-Shell, MT C-Shell, Micro Make, and Micro C-Tools.

Both ANTIC SOFTWARE and STart were present, though in seperate booths. Antic had no new ST programs to demonstrate, though I did notice "Interiors Design Disk", a CAD-3D collection of chairs, shelves, and other such forms. They also announced that the GFA BASIC 3.0 compiler will be available in June/July.

ST-LOG and STart were offering discount subscription rates.

DISCLAIMER:
There were many other firms and dealers who were present who I did not

mention above, due to either ignorance, forgetfulness, or misinformation. If anyone wants to correct/add on to this, go ahead.

BESIDES THE BOOTHS...
Sig Hartmann gave a speech to a packed crowd on "the future of Atari". He reaffirmed Atari's policy of not announcing any product "unless it will be available for sale within 60 days". Thus, while he acknowledged some truth to the rumors regarding the Atari TT, the ATW, an Atari networking system, and new graphics resolutions, he did not say anything specific. Sig also reported that the US market will get the FIRST shipments of the STacy and the Portfolio, to the tulmultious cheer of the crowd.

Atari personnel also reaffirmed their desire to "attack" the US market in 1989, primarily through the STacy, the PC Portfolio, and increased public relations. Though their advertising budget "has tripled", Sig says that Atari will keep advertising in the hands of local district managers. Thus, no prime-time nationwide commercials or TIME Magazine spots in the near future.

Though I had to leave before this happened, there is/was a music concert scheduled for 7:30pm on April 22. Only 1000 people allowed in, with tickets at $5 each. Music by Mick Fleetwood and Michael Pinder (of Moody Blues) was supplemented with a limited-engagement showing of the STacy (it's up and running), the PC Portfolio (also), and the first public playing of the new Holtz MIDI Board.

Anyway, it was a lot of fun, even though the freeway drive was terrible (this IS Los Angeles, right? B-), and Disneyland's prices were extortionary. There is already talk of another World of Atari Show next year; I sure hope so!

I have only received one response to my previous posting about
PaperClip.

I am willing to pay $$ for an old package of PaperClip w/spelling checker
to anyone who still has a copy around.

I know nothing about 8bit software in the last 5 years, so I would
like a recommendation of a word processor for my brother who has a 130XE

Any good word processors that have spelling checkers that will let you
add your own words, and will make use of the extra memory in the XE?
(actually it is a 327K XE upgraded...)

Thanks for any recommendations...

I haven't purchased STart in over a year, so I was suprised to
see a new Amiga magazine in my local bookstore's shelf,with "Antic"
on the cover.

I'm not mad (*please,PLEASE* don't start that stupid "war" again...)
but I am puzzled. Why would they do something like that? If that brings
in more revenue, then great. But since reading Antic from their first year,
I can't imagine them publishing anything but an Atari magazine (at least
with "Antic" on the cover.)

The only thing I can figure is new owners. Kinda a switch from
a few years ago. Antic (named after and Atari chip) making a Commodore-
only mag, and "LFP" rescuing Analog. What's next?

-Marty

Actually, Antic has published an Apple][magazine for a while now. Just
check the publisher of II Computing. They also sell software for the
Amiga, through the Catalog.

I have an Indus GT for the atari 8-bits which is in need of repair (the belt which links the motor to the mechanism turning the disk needs to be replaced).

Unfortunately, I have lost track of Indus since I bought the drive about 3 years ago (do they still exist?) and have no current address or phone number. Can someone either send me the current address/phone # of Indus or recommend a good place within New York City that does repairs? Thanks.

>..
>Finally. I still can't read PC-DOS disks. Are they in 256-byte sectors?
>Is there some other incompatibility that will stop me? How do I find
>out?

Hi Stan!

A little tutorial upon Atari DOS, also interesting for those who wonder why
it is so hard to write software for an Atari to read/write PC-format...

First of all, there is the BOOT PROCESS: When an Atari is turned on, it
polls the serial bus for the presence of a drive. If it finds a drive,
it loads the first three sectors, called the BOOTSECTORS. These sectors
contain a piece of code (called the BOOTSTRAP), to load the rest of
DOS.SYS. This code will be executed right after it is loaded. The code
to read the bootsectors is in the ROM of the Atari and originates from
the early days of the machine. When they had 128 byte sectors... This
explains why, even on a DD (=256 byte sectors) disk, the first three
sectors _have_ to be SD. On a DD disk the bootstrap does not only contain
code to load DOS.SYS, but also code that replaces the OS-routines for
sector I/O, thus allowing the next sectors to be of another density.
Quite logical, isn't it?

This is an answer to your first question. And to your second: No DOS can
ever write DD bootsectors, since the Atari OS _requires_ SD bootsectors.

Then there are some physical differences between Atari disks and PC disks.
Atari uses SS, 40 track, 18 sectors/track, 128 (or 256) bytes/sector,
versus (SS XT floppy) 40 track, 9 sectors/track, 512 bytes/track on a PC.
An unmodified 1050 (I do not know anything about the XF551) can _ONLY_ read/
write 128 byte sectors. When those drives came out, Atari advertised with
its capability to read/write E(nhanced)D(ensity) disks. They just crammed
26 sectors in a track (40*26*128=130K, vs SD:40*18*128=90K). As far as I
have understood, the new (after my Atari time, so that's new to me :-)))
XF551 can read/write 256 byte sectors, BUT THAT IS STILL NO 512 !!!

To make things even worse, a PC drive uses the index hole of a disk to
determine which sector is the first of a track. The 1050 makes that sector

(about) twice as long... This should answer your third question...
Sorry, but there is only one way to make an Atari drive read/write PC format disks: MODIFY THE DRIVE!!. The Atari drives contain a 6508, which is in fact a baby-6502(smaller casing, smaller address space), some ROM (containing software to perform its tasks, ie read/write, communicate with the Atari over a serial line, format a disk etc..), some RAM for sector buffering (only 128 bytes in a 1050..) and the very same disk controller as used in the PC (a WD1793, I believe). So the controller can be programmed to read/write PC format, but only by changing the code in the ROM of the drive....

DON'T PANIC: You don't have to do this all, it has been done allready!! There is an upgrade available for Atari drives, the Happy controller, which does all the things described. It was originally meant to boost the capacity of the slow 1050 and 810 drives. It does not only double the storage capacity, but also speeds things up quite a bit. I have heard that they ship their Happy Controller with software to read and write PC format disks!! Sorry, but I do not have their address.....
(too bad...)

Ciao!

Michel J. Waucomont.

DISCLAIMER: All the knowledge about the Atari 1050, it's internals and how to control it are reproduced from memory. The last time I have seriously been working with an Atari is about two years ago. This should explain my lack of knowledge about their latest products (XF551) and some of the inaccuracies, which might be in this article. The recent purchase of a second hand 800XL w. 1050, which happened to be equipped with a Happy controller, just revived my interest in the machine. Furthermore, I have got nothing to do with Happy, other than being a satisfied owner of a product of them...

2163. The SX212 and Kermit65

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-24 20:39:12 UTC
From: cs1551cu@hydra.unm.edu
Message-ID: <4927@charon.unm.edu>
Source record: 115817

Well, I've downloaded Kermit65 from score.stanford.edu,
uudecoded it, and unarced it...
Well....it's not working once I go into the terminal mode...
I have an SX212 modem with SIO connection to my Atari 130XE, and I have
what I thought was the R: handler from the SX212 Companion! for working
with the 850 EXPRESS terminal program, but it didn't work.
So, I went over to my local Atari dealer (Plaza Computers) and we
tried using the P:R: Connect as the go-between...we tried all sorts of
combinations to make it work, from using the KERMIT.COM with
the PRC.SYS file (which is supposed to make any program for the 850 work
on the P:R: Connect) to using the KERMITNR.COM with any handler, including
the SX212A file (found with the SX212 Companion), we did get some response
from the terminal when we used plain atari (none) emulation, but
it was only error messages and the cursor appearing and dissapearing..
Does anyone have any idea what could be causing this problem?
Also, if someone has a true or better R: handler for the SX212, I would
love to know who you are.. I would appreciate ANY thoughts or help
on this, as I NEED a vt100 emulator real bad!! BTW, I got the vt10sqr
emulator to talk to the modem, but it just takes the first input
and repeats it for ever...

Thanks a lot,

M c B Marc Bluefire <aka cs1551cu@hydra.unm.edu>

The magazine title is actually "Antic's Amiga+".

I would imagine that the publishers see a potential market and are therefore
attempting to garner additional business.

Ditto on the "no war" plea. Both machines have their advantages.

There hasn't been a change of ownership at Antic. They haven't
been an Atari only company for several years. They used to have an Apple
mag and a R/C Model mag, I know the Apple mag is gone and think the R/C
one is also.

They (actually Jim Capparell(sp)) started an Amiga mag because
the Amiga is a rapidly growing market. That means they should have a
lot of growth and profits for their Amiga mag. I know the 8 bit mag is
selling into a shrinking market, I'm not sure about "STart" since I
haven't been tracking the circulation numbers recently. (All I ever
look at is Dave and my column, so I know which was was published this
month.)

Actually you could make a reasonable case that Antic should only
publish mags about the 8 bit Atari's and the Amiga since both were
designed by the same person.

I have a used SuperForth-64 from Parsec research that I'd be willing to
part with for $40.00 (I paid $100 a few years back). It's an outstanding
implementation - I just discovered that I didn't like Forth, the language.
Contact me via email if you're interested.

2169. pc <--> Atari disk conversion

Newsgroup: comp.sys.atari.8bit
Date: 1989-04-26 07:11:46 UTC
From: rcbamw@eutrc3.UUCP
Message-ID: <610@eutrc3.UUCP>
Source record: 115824

Recently I posted an article explaining why it is __impossible__ to
write software for an Atari to make it read/write MS/DOS format disks.
It points out that to achieve this, a hardware modification to the
drive is needed.
The SUBJECT field read 'Re: More on SIO' though...

This does not *clearly* indicate that the contents is of interest to
anybody interested in transfering files from Atari to PC and vice versa,
so many might just have skipped the article...

So if you want to know more about reading/writing PC format on your
Atari, read article <604@eutrc3.UUCP> with subject:Re: More on SIO.
(SIO:Serial Input Output...)

Actually the featured product at the BDT booth was TURBOPOS, our new
multiuser business package. We also featured Hard Disk Toolkit and
Hard Disk Sentry; and we did have MT C-Shell and the Visual Shell
running on a Mega-4.

Also there was a meeting on TOS 1.4. Sig said that it was out for
ROM production and that devlopers would be able to get PROMs "soon"
at about $50. The implication was that it may be six months or more
before ROMs are readily available to end-users. No discussion of
